Blockade of the principal sources of tin supply, long feared by students of the United States tin industry, was in sight at the close of 1941 and became a reality early in 1942, precipitating a serious raw-material problem. The Japanese attack on Pearl Harbor on December 7, accompanied by a renewed drive on southeastern Asia, initiated the assault on the world's richest tin-producing area, which was climaxed by the fall of Singapore on February 15, 1942. At the outset of the Japanese offensive, it was widely believed that Singapore was virtually impregnable or at least could hold out long enough to permit completion of United States stock-piling objectives. The amazing speed and success of the Japanese conquest, however, forced the United Nations to drastically adjust their tin-consumption programs downward.

The immediate shock of sharp curtailment of imports into the United States fortunately could be cushioned because of the abnormally large stocks of tin on hand. Despite its late start, the Government stock-piling program had made substantial progress, and industry had been farsighted enough to greatly increase its inventories during recent years. As a result, 107,600 long tons of metallic tin were on hand when Singapore fell—enough for 17 months' consumption at a normal rate of use and sufficient to assure many more months' supply, if uses were restricted to absolutely essential purposes. The Government tin smelter at Texas City was nearing completion, with adequate stocks of ore on hand to assure its operation for several months. As a hedge against possible destruction of British smelters, the initial capacity of the Texas plant was being increased so that it could treat the entire Bolivian output, if necessary. These events, plus prompt Government action in placing all tin in the country under rigid control and in expediting its conservation program, give assurance that enough tin will be available for military needs essential to successful prosecution of the war, although domestic industry and

civilian consumption will undergo severe readjustments. Fortunately these need not be so abrupt as to cause violent disruption of industrial processes.

The forlorn outlook for obtaining any substantial quantity of tin from domestic sources has emphasized the importance to the United States of the Bolivian tin industry, not only from the viewpoint of maintaining or increasing production in that country, but also of safeguarding shipments of ore from submarine attack. Neither of these objectives was in sight on August 1, 1942. Bolivian production was reported to be declining because of labor shortages and rising costs, and the record of ship sinkings since December 7, 1941, is ample evidence that the submarine menace was far from being under control.

Statistically the tin industry of the world established several new records. Mine production exceeded the previous peak reached in 1940 by about 3 percent, and despite the inactivity of Continental European plants smelter output about equaled the previous high. World consumption is estimated to have increased about 3 percent over 1940 but was still below the record of 1937. Consumption of virgin tin in the United States in 1941, however, reached the unprecedented total of 106,000 long tons (processed); during October virgin tin was being used at the rate of 114,000 tons a year. Imports also touched a new high of nearly 141,000 tons, which permitted the substantial increase in stocks previously mentioned. Considering the momentous developments in the tin trade during 1941, prices fluctuated within extremely narrow limits—from a low of 50.10 cents a pound (Straits tin, New York) to a high of 55.00 cents. The Metals Reserve Co. buying policies under its agreement with the Tin Cartel were a restraining factor on the low side, and pressure from Government price-control agencies served similarly on the high side. A ceiling price of 52 cents a pound was established by the Office of Price Administration and Civilian Supply on August 16, 1941.

Salient statistics for tin in the United States, 1925-29 (average) and 1937-41

AXIS CONTROL OF WORLD TIN RESOURCES

As a result of events in 1941 and early 1942, the Axis gained control of the bulk of the world's tin resources. At the outset of the war in 1939, Germany, Italy, and Japan controlled less than 3 percent of the mine output, but with the Japanese conquest of Indochina, Thailand,

British Malaya, Netherlands Indies, Burma, and parts of China, as well as German domination of Europe, the Axis Powers occupied territory that produced 66 percent of the 1940 output. Although this success has assured Japan of tin supplies ample for prosecuting the war, Germany, whose tin supplies are believed to be very low, probably will not profit greatly because of the lack of communications as long as the British fleet controls the Indian Ocean. The chief significance of the shift in control is thus the loss to the United Nations of supplies of an important strategic material. Serious as this is, it is by no means decisive because of the tin ores available in areas still accessible to the Allies, chiefly in Bolivia, Nigeria, and Belgian Congo, which, it has been estimated, will produce approximately 90,000 tons of tin in 1942. Smelting capacity ample for treating these ores soon will be available to the United Nations.

From the longer viewpoint, the delay in rehabilitating mines in the war-torn tin-producing areas after the war is significant. The destruction of mines and equipment by the retreating British and Hollanders, plus the damage that will be inflicted as the Japanese are forced to retreat, will be such that it has been estimated 5 years will be required to restore production to normal.

GOVERNMENT STOCK-PILING PROGRAM

At the beginning of the year all Government tin purchases for stock-piling purposes were being made by the Metals Reserve Co., a subsidiary of the Reconstruction Finance Corporation. Buying continued under the 1-year contract made with the International Tin Committee on June 28, 1940. (See Minerals Yearbook, Review of 1940, p. 669.) In May 1941 the contract was extended to July 1, 1942. The contract provided that the United States agreed to buy all surplus tin offered up to 75,000 long tons a year. Actual purchases were far below the 150,000 tons possible under the contract, because of the abnormally large acquisitions by industry during the period and the fact that world production did not meet expectations. Under the first agreement, the International Tin Committee undertook to increase output to 130 percent of standard tonnages for 1 year, effective July 1, 1940, permitting participating countries to export 272,310 tons for the period. In the 12 months ended June 1941, exports actually totaled 235,074 tons, a 20-percent increase over the 195,834 tons shipped in the preceding 12 months. At the end of 1941, Metals Reserve purchases totaled 65,756 tons, of which 43,511 tons were delivered, 2,700 tons afloat, and 19,545 tons contracted for but not shipped. As of August 15, 1942, over 20,000 tons of Far Eastern tin purchased under the contract were still undelivered.

The Metals Reserve Co. also has commitments for the acquisition of 36,000 tons of tin under the loan agreements to China mentioned in Minerals Yearbook, Review of 1940, but as of December 31, 1941, no deliveries had been reported.

Despite assurances by the Office of Production Management early in July [1] that stock piles would be reserved for defense purposes and that they would not be drawn upon for any instant needs, Metals Reserve Co. began releasing tin to industry during August 1941 when shortages occurred in spot tin owing to shipping delays and Russian

[1] Office of Production Management, Memo to editors: PM 681, July 8, 1941.

purchases in the East. The total quantity released during 1941 was 905 long tons, which left a balance of 42,606 long tons on hand at the end of the year. The 5,478 tons and the 1,955 tons acquired and stored by the Procurement Division and Navy Department, respectively, have remained intact. Thus, at the close of 1941 the Government held 50,039 tons of tin in reserve compared with 20,804 (revised) tons at the close of 1940. In addition, there were 2,700 tons afloat and 55,535 tons contracted for but undelivered.

GOVERNMENT ORE PURCHASES

The United States acquired substantial quantities of tin ore in 1941 under the Metals Reserve Co. contract with Bolivian producers signed November 4, 1940. In addition, the company made an agreement in August 1941 with Netherlands producers for the acquisition of concentrates containing 20,000 long tons of tin from the Netherlands Indies, and contracts for small tonnages were signed with Mexican and South African producers. On June 30, 1942, retroactive to January 1, 1942, the Bolivian agreement was amended by changing the buying price from 48½ cents, f. o. b. U. S. ports, to 60 cents, f. o. b. Chilean and Peruvian ports, and providing for acceptance of concentrates equivalent to 30,000 tons of tin a year in contrast to the 18,000 tons agreed to originally.

By the end of 1941, 45,572 tons of ore had been delivered to the stock pile; 38,368 tons were derived from Bolivia, 7,159 tons from the Netherlands Indies, and 45 tons from South Africa. In addition to the quantity delivered, 251, 623 tons had been purchased or contracted for, including 226,652 tons from Bolivia, 21,341 tons from the Netherlands Indies, and 3,620 tons from Mexico. Data on the tin content of these delivered ores are not available.

Imports of Bolivian ore were begun in April 1941, when ores containing 2,330 tons of tin entered through the Galveston customs district. In September ores from the Netherlands Indies began arriving through New Orleans. The total tin content of ores imported during the year through Galveston and New Orleans was 27,368 long tons, including 21,148 tons from Bolivia and 6,220 tons from Netherlands Indies.

GOVERNMENT TIN SMELTER

Plans for the Government tin smelter at Texas City, Tex., construction of which was begun in October 1941, have been changed. Originally it was designed to treat 50,000 tons of Bolivian ore for the recovery of 18,000 tons of tin a year, but subsequent plans called for 30,000 tons of metal a year from Bolivian ores and 22,000 tons from high-grade alluvial ores. As of August 15, 1942, further extensions to raise the total metal capacity to 74,000 tons a year had been authorized. The expansion was prompted as a precaution against possible destruction of British smelters by bombing or sabotage.

Production of metal from high-grade Netherlands ores began in April 1942, and presmelting treatment of impure Bolivian ores was expected later in the year. The plant is operated by the Tin Processing Corporation under a contract with the Metals Reserve Co.

CONSERVATION

The formal announcement of Japan's alliance with the Axis accentuated the threat of a blockade on tin supplies from Asia and emphasized the need for developing a conservation and substitution program in the United States. In March 1941 the National Academy of Sciences was requested by the Office of Production Management to report on the possibilities of conserving tin. The task was assigned to H. W. Gillett, who worked with a committee under the chairmanship of Zay Jeffries. The formal report, submitted in June, contained many recommendations that subsequently formed the basis of various conservation orders issued by the Government. The report was published by Metals.[2]

By March 1941 the conservation aspects of raw materials reached such importance in the supply situation that a conservation unit was established in the Production Division of the Office of Production Management to direct Government activity in this field. In May 1941, following representations from the industry, producers and consumers of tin plate were called upon to adopt measures for conserving tin by using for certain packs only 1.35 pounds of tin per base box (for years the standard coating on tin plate has been 1.5 pounds per base box), substituting terneplate for tin-coated containers wherever feasible and using black plate wherever tin plate and terneplate were not required. Order M-21e, issued February 4, 1942, established further reductions to 1.25 pounds per base box for ordinary hot-dip plate and 0.50 pound for electrolytic plate; restricted the use of terne metal to terneplate only; and set up a quota system for using tin plate and terneplate. The tin content of terne metal used for terneplate and cans was limited to 15 percent by weight and that used for long ternes to 10 percent. Approximately 90 percent of the tin plate produced is utilized for making containers or cans.

Events following Pearl Harbor necessitated prompt and drastic reduction in the use of tin. On January 27, 1942, can manufacturers were ordered by telegraph to curtail sharply the manufacture, sale, and delivery of tin cans for such commodities as beer and confections in February 1942 to 50 percent of the quantity used for these products during February 1940. This order was superseded by Conservation Order M-81, issued February 11, 1942, in which can sizes were standardized, small sizes being eliminated. A general restriction was imposed on consumption of tin plate by designating the percentage that can be used for various canned products. No limit was placed on cans for fruits, vegetables, milk, and fish of primary importance, which would spoil if not canned when fresh and on which the Department of Agriculture had set production goals. In March 1942 the use of tin containers for nonessential products was discontinued. This group included beer, dog food, dried beans of all kinds (including pork and beans), baking powder, cereals and flour, petroleum products, candy, condiments, and tobacco. Conservation Order M-104, issued April 3, 1942, and Amendment 1 of April 20 restrict use of tin plate and terneplate as covers for glass containers, including crown caps for beverages and cover caps for home preserving.

[2] Gillett, H. W., Tin Conservation and Substitution: Metals, July 1941, pp. 6-9; August 1941, pp. 6-9; and September 1941, pp. 6-12.

Use of tin in products other than tin plate or terneplate has also been restricted. Drastic reductions in the consumption of tin in tin foil, tin alloys, tin oxide, type metal, collapsible tubes, etc., have been ordered by the Government. Tin content of solder has been reduced to a maximum of 30 percent, effective May 1, 1942. The use of tin in numerous articles, such as musical instruments, automobile body solder, office staples, jewelry, kitchen equipment, etc., during the first quarter of 1942 was limited to 50 percent of the amount used in the same quarter of 1940 and prohibited thereafter.

Order M–115, issued April 1, 1942, eliminates the use of collapsible tin tubes for foods, cosmetics, and many toilet preparations. Individuals purchasing tubes of toothpaste or shaving cream must turn in an empty tube for each new tube bought. Pure tin tubes are permitted only for certain pharmaceutical preparations. The old tubes are to be salvaged through the Tin Salvage Institute as agent for Metals Reserve Company.

INVESTIGATION OF DOMESTIC TIN DEPOSITS

The Bureau of Mines and the Geological Survey continued their investigation of domestic tin deposits. In May 1941 the Bureau of Mines issued a summary [3] reporting progress in its tin-exploration program, which contained the following conclusion:

> Two of the largest known tin-bearing areas in the country were explored, one in South Dakota and the other in southwestern New Mexico, which confirmed the opinion that no deposits are likely to be found in the United States that can supply any substantial quantity of tin even at prices several times the normal present price.

Deposits near Spokane, Wash., containing both tin and tungsten, were explored by the Bureau of Mines by surface trenching. According to a press release of the Geological Survey dated August 18, 1941, the largest deposit exposes about 500 tons of ore containing about 3 percent tin, and the presence of perhaps 20,000 tons of lower-grade material has been determined. The deposits have been known since 1906, and by 1912 about 150 tons of material containing 3 to 6 percent tin had been mined and stacked on the dump. There are no recorded shipments from this property.

The Coosa County (Ala.) tin belt, which was examined by the Bureau of Mines in 1939, was reexamined early in 1942 to determine whether recent developments had indicated continuity of tin-bearing pegmatites. Extensive trenching revealed little continuity and no appreciable amount of cassiterite.

The Geological Survey reported in August 1941 that its examination of virtually all known tin deposits from Lincolnton, N. C., southwest to Gaffney, S. C., showed that the bedrock deposits, individually or as a group, cannot yield more than small amounts of tin. Possibly a few can be worked profitably on a small scale if the price of tin rises sufficiently. In 1939 the Bureau of Mines conducted concentrating tests on a sample of tin ore from North Carolina.[4]

Tin deposits near Battle Mountain, Lander County, Nev., were described in a report by the Geological Survey,[5] which concluded that

[5] Fries, Carl, Jr., Tin Deposits of Northern Lander County, Nev.: Geol. Survey Bull. 931–L, 1942, 15 pp.

selective mining of the tin-bearing veinlets would not pay, owing to their narrowness and discontinuity, and it seems equally certain that the deposits could not be mined by bulk methods. A few tons of cassiterite might be recovered from veins by narrow stoping and hand sorting, and from thin placer deposits of gravel in small pockets. This tin-bearing area was described in a Bureau of Mines report in 1939.[6]

At Majuba Hill, Pershing County, Nev., cassiterite appears widely scattered in very small amounts and is abundant only in a single underground ore shoot so small that it could not be mined at a profit.[7] As now exposed, the shoot, which is cut off by a fault, may contain 12,000 pounds of metallic tin. Its utilization depends on finding additional ore reserves by prospecting aimed at locating the offset part of the high-grade shoot, discovering additional shoots or a large body of low-grade ore.

The results of a study of the tin deposits of Irish Creek, Va., by the Geological Survey, announced in April 1942, suggest that further prospecting in the area may be warranted. As only a small part of the district has been explored, the extent of its tin deposits is still undetermined. The Geological Survey has done some work on tin deposits of the Temescal district and the Bernice group of claims near Cima, San Bernardino County, Calif. A shipment of low-grade tin ore from the Cima property is understood to have been made in 1942 to the Tin Processing Corporation. A systematic survey of all known tin occurrences in California has been made by Segerstrom,[8] who states

> The future of tin mining in California, unfortunately, does not look encouraging. Repeated failures in operations that have been attempted, lack of ore bodies of suitable size and value, lack of reports of new and substantial occurrences, all add up to a general dismissal of possible future operations in this State.

The tin-bearing pegmatites of the Tinton district, South Dakota, were reported on by the Geological Survey.[9]

In 1941 the Geological Survey sent geologists into the Seward Peninsula and the Hot Springs district to make intensive investigation of all possible sources of tin there. Although these investigations have not yet been completed as of August 1942, none of the parties has found deposits that appeared to contain a large supply of tin that could be worked at a profit under existing conditions.

On May 25, H. R. 7131, authorizing the Metals Reserve Co. to purchase for the United States all tin produced in this country at $1.00 a pound, was introduced in the 77th Congress, 2d Session, and referred to the Committee on Mines and Mining. H. R. 96, authorizing an appropriation of $2,000,000 for exploration and development of Alaska tin deposits, was introduced January 3, 1941, but no action was taken.

In March 1942 the Reconstruction Finance Corporation announced the adoption of a plan to encourage producers to speed development of small ore deposits containing strategic and critical metals and

minerals. The owner or lessee of properties giving reasonable promise of success may now obtain an initial loan without mortgage of not more than $20,000, repayable out of proceeds from production. If the results of such development are favorable, additional loans up to $20,000 may be made for further development.

LICENSING OF EXPORTS

The Department of State issued no licenses for export of tin-plate scrap during 1941. Exports of all other tin-bearing commodities are subject to controls and license by the Board of Economic Warfare, except those authorized by the Office of Lend-Lease Administration. Data on the quantity of tin authorized for export have not been released.

DOMESTIC PRODUCTION

MINE OUTPUT

Only 63 long tons of tin were produced in 1941—an increase, however, of about 28 percent from 1940. Alaska again supplied virtually all the output. According to the Federal Geological Survey, tin mining in Alaska in 1941 was confined mainly to placer deposits that have been developed in the western part of the Seward Peninsula near Tin City. It is understood that dredging operations in that area have now been suspended and equipment dismantled. Small amounts of stream tin were recovered in the course of placer-gold mining in the Hot Springs and Ruby districts of the Yukon region. No lode tin was mined during 1941 from any Alaska deposits.

In addition to Alaska, small quantities were reported produced in Alabama, Montana, New Mexico, and South Dakota in 1941. Producers included the Coosa Cassiterite Corporation near Rockford, Ala.; George A. Mayer near Basin, Mont.; W. Barker and W. A. McCalla, Paul D. Bellamy, Curtis C. Johnson, and H. E. Van Sant in the Black Range, N. Mex.; and the Black Hills Tin Co. near Tinton and Black Hills Keystone Corporation near Keystone, S. Dak.

A historical table of mine production of tin in the United States, by States, from 1910 to 1938, inclusive, was published in Minerals Yearbook, 1939 (p. 679).

Mine production of tin (content) in the United States, 1937–41, by States

Year	Long tons				Value
	Alaska	South Dakota	Other States [1]	Total	
1937	166	0.8	1.6	168.4	$205,300
1938	94	1		95	90,000
1939	33	.5	.5	34	38,400
1940	46	2	1	49	54,900
1941	[2] 53.4	1.4	8.1	[2] 62.9	[2] 73,200

[2] Subject to revision.

DOMESTIC TIN SMELTING

Tin ores were treated on a small scale in this country in 1941. Several privately owned plants recovered 1,839 long tons of tin, includ-

ing 502 tons in the form of pig tin and 1,337 tons in the form of alloys (mostly solder) made direct from the ores. In 1940 (revised figures), 1,391 tons were recovered—510 tons as pig and 881 as alloys. The total recovered was 32 percent greater than in 1940, the production of pig tin being slightly less while that of tin alloys increased 52 percent. The Government plant at Texas City, Tex., did not begin producing pig tin until April 1942.

The ores treated at domestic plants in 1941 were obtained chiefly from Latin American countries, principally Bolivia, although small quantities produced by domestic mines were also purchased. Companies reporting the recovery of tin from ores in 1941 include American Metal Co., American Smelting & Refining Co., Franklin Smelting & Refining Co., Kansas City Smelting Co., Metal & Thermit Corporation, Nassau Smelting & Refining Co., Phelps Dodge Refining Corporation, and Vulcan Detinning Co.

SECONDARY TIN

Recovery of secondary tin established a new record in 1941, with a 27-percent increase over 1940. The increase was due principally to greatly accelerated industrial demand prompted by the national defense program and higher prices. In appraising the significance of secondary tin as a factor in national supply, it should be borne in mind that a very large proportion (approximately 80 percent in 1941) is contained in alloy scrap from which the tin seldom is isolated but merely revolves in the various cycles of use, purification, and re-use of the alloys themselves.

Secondary pig tin recovered by detinning plants in 1941 totaled 4,500 tons (3,700 tons in 1940), mostly from clean tin-plate scrap with only a small tonnage (about 60 tons) from old tin-coated containers. Further details on secondary tin are given in the chapter on Secondary Metals—Nonferrous.

Secondary tin recovered in the United States, 1925–29 (average) and 1937–41

Year	Tin recovered at detinning plants			Tin recovered from all sources			
	As metal (long tons)	In chemicals (long tons)	Total (long tons)	As metal (long tons)	In alloys and chemicals (long tons)	Total	
						Long tons	Value
1925–29 (average)	900	2,000	2,900	7,500	23,100	30,600	$38,034,120
1937	2,500	1,500	4,000	7,400	19,700	27,100	32,124,100
1938	2,200	1,300	3,500	4,300	16,700	21,000	19,284,600
1939	3,600	600	4,200	4,000	22,000	26,000	29,276,600
1940	3,700	600	4,300	4,500	25,200	29,700	33,102,400
1941	4,500	950	5,450	5,300	32,200	37,500	43,722,700

CONSUMPTION

APPARENT CONSUMPTION

The apparent consumption of primary pig tin is determined by adding domestic smelter production to net imports. As there was no recorded smelter output from 1925 to 1939, inclusive, the apparent consumption for this period was equivalent to net imports. The

computation does not consider fluctuations in dealer and consumer stocks (information on which is not always available) or the large accumulation in Government stocks; consequently the figures do not reveal the actual trend in consumption. Nevertheless, statistics on apparent consumption have been useful in determining long-time trends. A table giving these data from 1910 to 1938 was published in Minerals Yearbook, 1939 (p. 680).

The apparent consumption of primary pig tin, computed by the above formula, reached an all-time record of 141,618 tons in 1941—a 15-percent increase over the 123,537 tons consumed in 1940—but, as indicated above, these figures exaggerate actual consumption because of very large increases in consumers' and Government stocks. Nevertheless, actual consumption of primary tin in 1941 reached a new peak, being considerably higher than in 1940, and exceeded by 15 percent the consumption of 1929, when the previous record was established.

CONSUMPTION BY USES

The following tables show the actual consumption of primary and secondary tin as reported to the Bureau of Mines. The items included in the table of consumption by uses represent the products of the first cycle of manufacture. In computing the figures shown in the table, any primary tin emerging from the first stage of manufacture as scrap was recorded as secondary metal. The figures thus understate consumption of primary tin, and some of the secondary tin listed duplicates the virgin metal shown because it is reclaimed from such byproducts as tin-plate clippings and virgin drosses from tin-plate and tinning mills and other plants consuming virgin tin. In 1941, for example, domestic consumers received 114,281 tons of virgin metal, of which 8,252 tons were added to inventories and 106,029 tons processed. Of the tin processed, about 4,200 tons were sold as scrap, lost, or added to stocks of metal in process, and the remainder emerged from the first stage of manufacture in the products shown in the following tables.

Consumption of primary and secondary tin in the United States, 1937–41, in long tons

	1937	1938	1939	1940	1941

[1] Primary includes small tonnage of pig tin derived from detinning operations; Bureau of Mines not permitted to publish separate figures.
[2] Small quantity included under "Miscellaneous."
[3] In 1937 pure tin tubing required 1,286 tons and tin-lined tubing 10 tons; not reported separately after 1937.
[4] Includes 454 tons of primary and 20 of secondary for Britannia ware and 64 tons of primary and 8 of secondary for pewter.

Tin is employed principally in the manufacture of tin plate. Normally this industry consumes approximately half of the virgin tin used in the United States. Tin-plate production rose to a new high in 1941, as the total food pack was the largest in history.

The use of primary tin in various other products increased as follows in 1941: Solder 77 percent, babbitt 68 percent, bronze and brass 85 percent, type metal 242 percent, collapsible tubes 21 percent, foil 151 percent, tinning 62 percent, pipe and tubing 100 percent, chemicals 438 percent, tin oxide 53 percent, and bar tin 53 percent. The use of primary tin for galvanizing declined 10 percent.

FOREIGN TRADE [10]

The principal items in the foreign trade of the United States in tin are imports of pig tin (which supply virtually all the domestic tin requirements) and exports of tin plate. In 1941 a large quantity of tin concentrates was imported and placed in storage for smelting at Texas City, Tex. Of minor importance are the import and export trade in tin-plate scrap; exports of tin-plate circles, strips, cobbles, etc.; and exports of waste-waste tin plate. There is also an appreciable export of miscellaneous tin manufactures, tin-plated hollow ware, and tin compounds.

Imports of metallic tin in 1941 were 13 percent greater than in 1940, establishing an all-time record. Of the total, 89 percent came from Asia, 8 percent from Africa, and 3 percent from Europe and Australia. Receipts from Asia increased 10 percent, and those from Africa more than doubled. Imports of tin concentrates (which were the largest since 1920) were consigned chiefly to the Government tin smelter at Texas City, Tex. The first shipment for treatment at this new smelter arrived in April. The tin content of the ores and concentrates imported was 28,670 tons from the following sources: Bolivia 22,021 tons, Netherlands Indies 6,220, Africa 198, Mexico 114, Argentina 102, and others 15.

Foreign trade of the United States in tin and tin concentrates, 1937–41

1939	12, 633	10, 204	6, 552	9, 132	99	311, 016
1940 [1]	16, 615	3, 536	4, 590	6, 091	137	383, 328
1941 [1]	22, 600	180	4, 952	8, 321	109	354, 940

[1] In addition, 15,153 long tons of terneplate clippings and scrap valued at $474,374 were exported in 1940, and 715 long tons valued at $43,545 in 1941, not separately classified before January 1, 1940.

Foreign trade in miscellaneous tin manufactures and tin compounds, 1937–41

Year	Miscellaneous tin manufactures		Tin compounds (pounds)	
	Imports [1]	Exports [2]	Imports	Exports
1937	$50, 545	$2, 532, 747	1, 715	218, 006
1938	19, 453	2, 064, 515	865	172, 467
1939	20, 106	1, 098, 140	5	204, 362
1940	12, 429	706, 425	271	131, 019
1941	2, 266	1, 456, 353	7, 224	137, 424

[1] Includes tin manufactures, n s p f, tin foil, tin powder, flitters, and metallics
[2] Includes tin dross and tin-bearing scrap material other than tin-plate scrap.

Exports of tin plate, etc., decreased 7 percent owing chiefly to loss of markets in Europe and Asia in consequence of the war. There were large increases in shipments to South America and Australia. For the 12-month period beginning December 15, 1941, 218,600 metric tons of tin plate have been allotted for export to Latin America by the Supply Priorities and Allocations Board at the request of the Economic Defense Board. Shipments to Latin America and Canada, which represented 58 percent of the total, increased 15 percent in 1941.

Tin plate, terneplate (including long ternes), and taggers tin exported from the United States, 1940–41, by principal countries and customs districts

PRICES

The average quoted price of Straits tin for prompt delivery in New York in 1941 was 4 percent higher than in 1940 but 4 percent under the 1937 average, which was the high for the last decade. On August 16, 1941, a ceiling price of 52 cents a pound was established by the Government. At the beginning of 1941 the quotation stood at 50.10 cents a pound, the lowest at any time during the year. By the middle of January prices began moving upward, at first fractionally and then sharply after the middle of February upon reports of an impending breach between the United States and Japan. The price reached 54.25 cents on February 20. This prompted the Office of Production Management to warn that bidding up of price would neither increase the total supply of tin in the country nor the amount available to particular consumers, no matter what they may

have paid for it. Consumers were advised that if supplies of tin from the Far East should be interrupted immediate steps would be taken to conserve domestic supply and that all stocks, whether in Government or private hands, would become subject to allocation upon the basis of national defense requirements. Prices dropped promptly to 51.25 cents on March 1 but rose again to 52.75 cents on March 20. A slight decline began the first part of April, as there had been a check in the German plans in the Balkans, the Italian fleet had suffered a defeat, and the British Army had met with some success in Africa, making the prospect of a Japanese move in the Far East much less menacing. Thereafter, as the progress of the war changed, prices again trended upward. In July aggressive moves by Japan into and around Indochina, the Vichy Government acceptance of Japan's occupation of that country, and freezing of Japanese assets by the United States and Great Britain caused sharp increases in price. On July 25 quotations reached the highest for the year—55 cents—an increase of almost 5 cents since the beginning of the year and more than 2 cents since July 1. As a result, the Office of Price Administration and Civilian Supply on July 28 warned that this increase might force imposition of a price ceiling on the metal in the near future and expressed the hope that prices would stabilize around the level of the Government buying price—50 cents a pound. At the same time the chief of the Tin Branch of the Office of Production Management requested consumers not to buy if their stocks exceeded by 50 percent what they held in June 1940. As a consequence, quotations promptly settled to 52 cents, nominal. Early in August, concern over shipments of tin from the Far East became so alarming (Russia began buying Straits tin in considerable quantity during August) that an inflationary situation developed which necessitated issuance of an order by the Office of Price Administration and Civilian Supply establishing a ceiling price of 52 cents a pound, effective August 16.

In London the monthly average price for standard tin, spot delivery, ranged downward from a high of £270.1 a long ton in March to the low of £255.8 in October. The average for the year approximated £261.1, compared with £256.4 in 1940. Dealings on the London Metal Exchange were suspended December 9. The price averaged £257.6 for the six market days that preceded the suspension of trading. The closing price on December 8 was £259.10. With the closing of the exchange, the British Government attained control of tin prices, supplying consumers with their essential requirements at a basic price of £275 a ton, for tin with a minimum of 99 percent, delivered at works. Singapore failed to function as a market after December 13. It was bombed by the Japanese on Sunday night, December 14, and penetrated by Japanese military forces on February 9, 1942.

STOCKS

Total year-end stocks of virgin tin in the United States in 1941, including metal afloat but excluding Government stock piles in the United States, were 4 percent below those of 1940. Visible supplies decreased 42 percent, while consumers' stocks rose 22 percent. Including tin afloat and Government stock piles, metal on hand at the end of 1941 was equivalent to about 13 months' supply at the average rate of consumption in 1941. In August the Metals Reserve Co. began releasing tin from stocks for industrial purposes. On December 18 all supplies of tin became subject to special allocation. Thereafter no tin, including metal afloat, could be sold or delivered without specific permission, and imports could be sold only to the Government. The Government stock pile of pig tin was greatly augmented,

so that by the close of the year 50,000 tons were on hand and in addition 45,600 tons of tin ore were awaiting treatment by the smelter, which was being rushed to completion at Texas City.

During 1941 the Bureau of Mines canvassed tin consumers to determine stocks and use. According to these reports, the consuming industry had 54,100 tons of primary pig tin at plants at the end of 1941, including 34,950 tons held by tin-plate manufacturers. The industry also had 2,700 tons of virgin tin in transit or warehoused in addition to 880 tons of secondary pig tin on hand at the end of the year.

Stocks of virgin pig tin in the United States, December 31, 1937-41, in long tons

	1937	1938	1939	1940	1941
Location of stocks:					
Afloat to United States [1]	7,678	4,150	12,663	22,627	[2] 15,000
At landings in New York [1]	4,106	1,837	2,415	6,106	3,129
In licensed warehouses in New York [1]	2,279	3,320	887	3,073	371
Total visible supply [1]	14,063	9,307	15,965	31,806	18,500

WORLD ASPECTS OF TIN INDUSTRY

WORLD MINE PRODUCTION

World mine production of tin appears to have established a new record in 1941 that exceeded the previous peak in 1940 by 3 percent. Complete official statistics for 1941 are unavailable, but reasonably accurate estimates of totals for the year can be made from the data at hand. Production in the countries participating in the International Control Scheme during 1941 was 4 percent higher than in

1940, whereas that elsewhere was 7 percent lower. The output of the unrestricted producers comprised 10 percent of the total in 1941 compared with 11 percent in 1940, 18 percent in 1939, and 11 percent from 1925 to 1929.

Japan's conquest has shifted the balance of world tin resources. In 1938 the Allies controlled approximately 97 percent and the Axis Powers less than 3 percent of world output, whereas countries under Axis domination in 1942 controlled 66 percent of the 1940 production and those controlled by or accessible to the United Nations 34 percent. Production of tin in 1942 by sources controlled by and available to the United Nations has been tentatively estimated at 90,000 long tons, as follows: Bolivia, 45,000; Nigeria, 15,000; Belgian Congo, 19,000; United Kingdom, 2,500; Australia, 3,500; and others, 5,000 tons.[11] The estimate excludes China because of doubtful access over the Burma Road.

World mine production of tin (content of ore), 1925–29 (average) and 1937–41, by countries, in long tons

WORLD SMELTER PRODUCTION

The large tin-smelting plants of the Straits Settlements and those of Netherlands Indies have been destroyed or put out of commission, as they have fallen into enemy hands. Nevertheless, during the greater part of 1941 these plants operated at a very high rate. The smelter at Penang stopped accepting ore only shortly before December 19, when the island was captured by the Japanese. At Singapore, smelting was slowed in December as shipments of concentrates from mines came to a standstill, and by the end of January 1942 it was reported that only clean-up work was being done. It is understood that by the time Singapore surrendered all tin at Palau Brani where the plant was situated had been sent away. Presumably smelting continued throughout the year on the island of Banka and did not cease until the early part of February 1942. Ores and concentrates continued to flow to the United Kingdom from Nigeria and Bolivia. Smelter capacity has been expanded in the Belgian Congo. South Africa has resumed smelting operations on a small scale, and in Canada a smelter of low capacity is under construction in British Columbia. Progress was made in constructing the United States Government tin smelter at Texas City so that production of tin was begun in April 1942.

World smelter production of tin, 1925–29 (average) and 1937–41, by countries, in long tons [1]

INTERNATIONAL TIN CONTROL SCHEME

With the close of 1941 the International Tin Control Scheme officially terminated. Although recommendation was made to extend it for another 5 years, the war with Japan prevented any reasonable chance for it to operate, and formal ratification by signatory countries has not been completed. The scheme was initiated

on March 1, 1931, for 3 years. Subsequently it was renewed for 3 years, and again for 5 years to December 31, 1941. The object of the control scheme was to balance production and consumption and prevent rapid and severe oscillations of price by fixing quarterly production quotas, based upon standard tonnages, according to variations in price and stocks. To overcome the time lag which prevented this from being done rapidly enough, so-called buffer stocks of tin were introduced. The first buffer stock, introduced July 10, 1934, and consisting of 8,282 tons, was profitably wound up at the end of 1935. The second stock of 15,000 tons was established July 1, 1938, and was liquidated the latter part of 1939. The scheme also included provisions for research with a view to stimulating tin consumption. The International Tin Research and Development Council was created with research facilities in England and later at the Battelle Memorial Institute, Columbus, Ohio, and with a statistical office at The Hague, Netherlands. In May 1940 the statistical work was transferred to England following the German invasion of the Netherlands. Publication of the statistics ceased at the close of 1941 owing to the war in the Pacific.

The quarterly quotas during 1941 were set at 130 percent of standard tonnage; this would have permitted participants to mine a total of 272,960 tons, virtually full capacity. Unfortunately, this fell short of accomplishment by about 20 percent, and only two countries—Netherlands Indies and Nigeria—could meet their full quotas.

The question of renewal of the control scheme was discussed during 1941. At a meeting of the committee in March, it was announced that a recommendation for continuation of the agreement for a further period from January 1, 1942, had been sent to the signatory governments, subject to certain adjustments. Satisfactory progress was reported at the September meeting, when a preliminary new draft was discussed. Revised standards calculated from actual outputs in the year ended June 30, 1941, were proposed and as announced at the time totaled 231,000 long tons compared with 206,970 tons under the scheme then in effect. Quotas of all participants were raised except those of Bolivia and Thailand, which were lowered. French Indochina was omitted from the list of countries participating. After further discussion, standards for all countries except Thailand were finally revised upward, and a new total was set at 251,400 tons. This was agreed to at a meeting of the committee in London December 1, 1941, and, although Thailand refused to accept, renewal for 5 years was nevertheless recommended. The standard tonnages proposed for the new agreement were:

	Old	*New*
Belgian Congo	15, 035	20, 178
Bolivia	46, 027	46, 768
Malaya	77, 335	95, 474
Netherlands East Indies	39, 055	55, 113
Nigeria	10, 890	15, 367
Thailand	18, 628	18, 500
	206, 970	251, 400

The standard tonnages agreed upon were based on exports from July 1, 1940, to June 30, 1941. The quota for the first quarter of 1942 was fixed at 105 percent, corresponding closely to the 130 percent

of the standard tonnages under the expiring agreement. Owing to the war in the Pacific, the agreement was not formally adopted.

Although the scheme has officially terminated, a framework of the organization has been retained and will continue to function informally.

WORLD CONSUMPTION

Apparent world consumption of tin in 1941 is estimated to have totaled 175,000 long tons—about 3 percent above 1940. Details by countries are unavailable. Estimated 1942 requirements of U. S. S. R. have been given as 15,000 tons and for the British Empire 35,000 tons, of which 25,000 would be for the United Kingdom and the remainder for other components of the Empire.

Apparent tin consumption of the world, 1926–29 (average) and 1936–40, by countries, in long tons [1]

REVIEW BY COUNTRIES

Argentina.—Both mine and smelter output of tin in Argentina was considerably less in 1941 than in 1940. According to Ross Field,[12] up to 1940 the Pirquetas lode mine had produced 6,399 metric tons of concentrates containing 1,742 tons of tin. The ore reserves, as of June 30, 1940, amounted to 72,978 dry tons with a tin content of 2,379 tons, which at the present rate of production will last 2½ years. The Pircas Creek placer high-grade gravel is nearly worked out, and plans have been made to work lower-grade dirt, which will prolong the life of the placer at least 4 years, possibly longer. Annual consumption requirements are estimated at 1,100 tons. There is an import duty of 0.27 peso per kilogram of metallic tin.

Australia.—Some of the smaller mines in New South Wales experienced a difficult period in 1941 through prolonged drought. The Ardlethan tin field in New South Wales, which has been of considerable importance, appears to be reaching its final stages. Some tin-

[12] Field, Ross, The Pirquetas Mine, a Tin-Silver Property in Argentina: Eng. and Min. Jour., vol. 142, No. 7, July 1941, pp. 35–39.

mining companies hitherto operating in Malaya are searching for mining properties in Australia. An increase in the price of tin in Australia to £A371 a ton (a rise of £A51 a ton) was announced on April 30 by the Commonwealth Economic Advisor to encourage increased production from low-grade deposits. It is proposed to establish a pool by allocating £A10 a ton for developing low-grade ores. It has been estimated that Australia will produce 3,500 tons of tin in 1942, all of which, it is assumed, will be consumed locally.[13]

Belgian Congo.—The production of tin in the Belgian Congo in 1941 exceeded that in 1940 by about 17 percent and almost equaled smelter capacity (which, according to latest pre-war statistics, was 15,000 tons a year). Some appreciable expansion in output is anticipated during the first 6 months of 1942, as production was to be at the rate of 105 percent of the 20,178 tons permissible annual figure proposed in the unratified control scheme. To increase output, all mining companies have been placed under direct State control. There are three important tin-producing areas—Katanga, Maniema, and Ruanda-Urundi. Tin concentrates are obtained from both lode and placer deposits. The Geomines smelter at Manono treats custom ores as well as company ores. The Symaf tin-mining concern was considering erecting a smelter at its property, but it is not known how far this progressed.

Bolivia.—Owing to Japanese occupation of Malaya, Netherlands Indies, and Thailand, Bolivia is now the principal source of tin for the United Nations. The tin content of ore exported from Bolivia in 1941 was 42,199 long tons compared with 37,940 in 1940. Despite the 11-percent increase, exports were 17,637 tons under the permissible quota of 59,836 tons allowed under the control scheme. About equal portions of the exports went to the United States (for treatment by the new smelter at Texas City) and to Great Britain. Production in 1941 was retarded by labor shortage and lack of railroad transportation from mines to Pacific ports. A standard of 46,768 tons was proposed for Bolivia under the new restriction scheme, which expired at the end of 1941. Production for 1942 has been estimated at 45,000 tons of tin. Few new mines have been discovered recently, and old mines are not being developed. The Director General of Mines of Bolivia has estimated 430,000 tons to be the total supply of tin available in Bolivia. Engineers of the United States Bureau of Mines have been studying the problem of accelerating output and improving the grade of concentrates produced. Most of the low-grade concentrates are shipped by small producers (the large producers include Patino, Hochschild, and Aramayo), who are without means for applying technical knowledge and modern methods to their mining operations. With proper development of their operations, the Director General of Mines predicts that Bolivia should be able to produce about 70,000 tons of tin annually. Recovery in the more efficient mills is 80 percent, while poorer mills obtain 50 percent or less and there are millions of tons of old tailings, mine dumps, and stope fillings assaying 0.6 percent tin or better—in some cases as high as 2 percent. P. H. Reagan states "the recovery of this metal offers an opportunity for the metallurgists who can solve the problem." [14]

[13] Tin (monthly bulletin of The Tin Producers' Association), February 1942, p. 1.
[14] Reagan, P. H., Bolivia. Eng. and Min Jour., vol. 142, No. 8, August 1941, pp. 156–157.

Upon the basis of increases in cost of production, transportation, and insurance, producers campaigned during 1941 for an increase in the price paid them for tin ore. The outcome of this resulted in an amendment to the agreement with Metals Reserve Co. on June 30, 1942, retroactive to January 1, 1942, changing the buying price from 48½ cents f. o. b. U. S. ports to 60 cents f. o. b. Chilean and Peruvian ports and providing for acceptance of concentrates equivalent to 30,000 tons of fine tin a year, suppliable at the option of sellers, in contrast to the 18,000 tons agreed to originally. Although Patino Mines and Enterprises Consolidated does not participate in the Metals Reserve contract it will profit by this new arrangement. Under provisions of a contract with the British Government, the company is entitled to receive settlement upon the basis of the Metals Reserve Co. buying price.

British Malaya.—On December 8 the Japanese invaded Malaya, landing at Kota Bharu airdrome across from the Thailand border in the northern part of the peninsula. Thereafter tin-mining activities were disrupted and ceased entirely as fighting raged toward Singapore. However, the rate of production at tin mines and smelters during the year up to December had been about the same or slightly higher than in the previous year. The 1941 quota for Malaya under the Tin Control Scheme was 100,536 long tons, but up to the end of November only 74,367 tons had been exported. As mine production virtually ceased in December, it has been assumed that total output in 1941 was 78,000 tons or about 9 percent less than in 1940. Ores imported for reduction at smelters in the Straits Settlements from sources other than Malaya during the first 11 months of 1941 totaled 37,293 tons compared with 39,643 tons in the same period of 1940 and 45,576 tons in all of 1940. During the first 10 months of 1941, the smelters shipped 108,855 tons of pig tin, which up to then had been exported at a rate a little above that of the previous year. On December 6 stocks of concentrates at Singapore and Penang are believed to have amounted to the equivalent of 9,975 tons of fine tin, slightly more than half of which was at Penang. Stocks of refined pig tin at Singapore and Penang on July 31 totaled 3,430 tons, of which about 80 percent was at Penang; these had been reduced somewhat, but as of November 30, the carry-over in the Straits Settlements exceeded 2,700 tons, of which about 75 percent was at Penang.[15]

Strict censorship prevailed during the latter part of 1941, and publication of figures relating to mine output was prohibited; but reports indicated almost complete cessation of mining operations toward the end of the year, owing to the Japanese invasion. Shipping difficulties also affected output, and enemy action caused the loss at sea of some mining equipment. With the advance of the Japanese army toward Singapore, shipments of concentrates from the mines ceased. Smelting slowed so that by the end of January 1942 the Singapore smelter was doing clean-up work only. By the time Singapore surrendered on February 15, 1942, all tin at Pulau Brani in Kepple Harbor where the smelter was situated had been sent away. Reliable information on the condition of the smelter (which had been the largest in the world) is not available, but it may have been damaged when the harbor was bombed. The smelter at George Town, Penang, stopped accepting ore only shortly before

[15] American Metal Market: Vol. 48, No. 249, December 30, 1941, p. 5.

the Japanese captured the island on December 19, so that it would seem that some tin fell into the hands of the invaders. Although there is no definite information on the quantity so acquired, reports have stated that 1,500 tons were awaiting shipment at the time, and Japanese statements have indicated that some 1,300 tons were thus obtained. It has not been definitely established whether the George Town smelter was destroyed, although A. Strauss & Co., Ltd., of London reported that it had been. The Japanese, however, have claimed that the smelter and furnaces were intact when they seized the island. The smelter at Butterworth (on the opposite shore of the mainland) was put out of action, according to the British Under Secretary of War.[16] This smelter was only reopened in June 1940 after remaining closed for 9 years during which it served as an ore-buying establishment. Dredges and other mining equipment and power plants were destroyed, however, as the British troops retired; and as long as war continues it will be extremely difficult for the Japanese to re-equip these plants. Some authorities consider that 5 years must elapse before complete recovery of output is possible.[17]

A Commission of Inquiry, appointed in September 1940 by the High Commissioner to investigate the management of the Mines Department of the Federated Malay States, disclosed corruption and bribery. A number of officers of the Mines Department have been prosecuted, convicted, and given prison sentences.[18]

Burma.—The property of Mawchi Mines, Ltd., 20 miles east of Toungoo, which is in territory occupied by the Japanese, is reported to have been put out of commission for at least 18 months before the staff departed.

Canada.—No commercial ore bodies of cassiterite are known in Canada. At present, however, tin is being produced from zinc tailings at the Sullivan mine, British Columbia. Occurrences of tin have been found in New Brunswick, Northwest Territories, Ontario, Manitoba, Yukon, and Nova Scotia. Tin was separated from Sullivan lead-zinc ore some years ago in experimental work by the Consolidated Mining & Smelting Co. of Canada, Ltd. The company, which has continued these experiments from time to time, states in its 1941 annual report that the tin concentration plant commenced operations on March 1, 1941, and functions very satisfactorily. The production of refined tin will commence in April 1942. The tin content of the ore is so small that its recovery is of more academic than commercial importance. * * * A process has been developed for the electric smelting of tin. According to H. R. Banks, superintendent, Sullivan concentrator, "On the basis of present operation the Sullivan production will approach 500 tons of refined tin per year." [19] The smelter is at Kimberley.

China.—No official records of Chinese tin output are available, although this country has been an important producer for centuries. Records have been confined to exports, which have averaged 10,000 long tons annually during recent years. The Minister of Economic Affairs of the Chinese National Government, Chungking, roughly

estimates that 17,278 metric tons of tin were produced in 1940 in unoccupied China.[20]

Nearly all the ore produced is smelted in China, although during the last 5 or 6 years small tonnages were being shipped to smelters in the Straits Settlements. Pig-tin imports have not been large, and very little is known about the quantity consumed. Since 1937 exports have declined steadily. Tin is a Government monopoly, and exports are controlled through the Yunnan Consolidated Tin Corporation and the National Resources Commission. The Government has been striving for an annual export of 15,000 tons of tin. Yunnan, Kwangsi, and Hunan Provinces are the principal sources, the bulk of the output coming from Yunnan. Estimates of production in Yunnan during the first quarter of 1941 were 1,352 tons, with stocks of about 7,000 tons on hand. Approximately 2,400 tons of pig tin were shipped to the United States via the Burma Road during the first 9 months of 1941.

A Chino-Russian barter agreement provides for repayment of Russian credits with shipments of tin and other materials from China to Russia. The United States, through the Metals Reserve Co., has arranged to purchase wolframite, antimony, and tin from the National Resources Commission of China to the total value of $90,000,000, but no tin had been received by Metals Reserve Co. for stock-piling up to the end of 1941.

Germany.—There are no important tin mines in Europe, and Germany formerly depended entirely on imports from the Far East and Bolivia for her requirements. Germany is believed to have had large stocks in 1938 and to have acquired additional stocks in the Netherlands. Substitutes have been developed for many uses, such as in the food-packing industries, and all available tin is reserved for highly essential applications. Germany has been outstanding in the reclamation of scrap tin and other metals for many years. Substantial amounts of cadmium, a substitute in some uses of tin, are produced in Germany and Poland. Despite these efforts to eke out a tin supply, some authorities assert that Germany is facing a critical tin shortage. According to Tin,[21] the official bulletin of the Tin Producers' Association—

> Germany's tin reserves must be fast diminishing. Her shipbuilding, aircraft building, and armaments program for 1939 and 1940, if it were as extensive as neutral observers would have us believe, must have almost exhausted Germany's reserves of tin. Whichever way one may approach the problem it becomes clearly evident that the tin shortage must be assuming alarming proportions in Germany. How long she can go on without tin, or whether she has successfully exploited a substitute are matters upon which it is naturally impossible to offer any concrete facts. Submarines, ships, aircraft, tanks, guns—all these things are virtually impossible without tin. Germany cannot go on producing war weapons unless she gets stocks of tin. Is she getting those stocks? From all statistics and information available it would seem that she is not. In fact, it would appear that Germany is now facing a severe shortage of tin. If this is so it is almost certain that we shall once again see a deterioration in her aircraft production, in her shipbuilding program, and, what is more important, in her fire power, both in bombs and shells. Experts talk glibly of Germany's shortage of oil and the effects of the food blockade, but the tin shortage may do more to sabotage Germany's war effort than either of them.

[21] Tin, Tin and Germany's War Effort: April 1941, p. 4.

Italy.—The tin resources of Italy are insignificant compared with requirements. It is reported that all tin-bearing equipment in public bars and restaurants has been requisitioned by the Government.

Japan.—On August 1, 1942, Japan possessed sources formerly supplying two-thirds of the world's tin, as a result of military operations begun with its attack on Pearl Harbor, December 7, 1941. The annual demand for tin in Japan in peace time was about 4,400 tons, of which 20 percent was supplied from its own mines and the remainder imported. Japan is believed to have accumulated a stock pile of tin before hostilities began, but war needs have probably increased to 12,000 to 15,000 tons a year, of which only about 5,000 tons can be supplied by Japanese smelting facilities. Therefore, unless the smelters in the Straits Settlements and Banka can be operated, Japan will be somewhat handicapped until its own smelting capacity has been increased. Ample ore is available in Thailand and Indochina to meet Japanese requirements. It has been reported that the refineries at Penang, Singapore, and Banka are to be operated by Mitsubishi Mining Co. and the Togo Mining Co.

Mexico.—The small quantity of tin produced annually in Mexico is obtained by native miners, chiefly from scattered deposits. A refinery of small capacity at San Luis Potosi produces pig tin, all of which is consumed in Mexico. Ores that cannot be treated in Mexico are sold for export. The Metals Reserve Co. has contracted for the purchase of 3,630 tons of tin concentrates from Mexico. By Presidential decree, effective July 15, 1941, exportation of tin from Mexico to any non-American country is prohibited. Tin deposits of Mexico recently have been investigated by the United States Geological Survey. The problem of concentrating low-grade tin ores is being studied with a view to establishing a central treating plant at Aguascalientes.

Netherlands Indies.—The permissible export quota of Netherlands Indies for 1941 was 50,772 long tons; up through November, 48,805 tons had been exported and as additional quantities were doubtless shipped during December the total for 1941 has been estimated at 51,000 tons, or about 18 percent more than in 1941. Production and smelting operations presumably continued up to the end of January 1942 or shortly before Japanese planes came over Banka on February 3. Japanese troops landed on the west coast of Billiton on April 10, 1942, according to a broadcast from Tokyo. The smelters on Banka were at Muntok, Pangkalpinang, and Belinjoe. It is believed the smelting plants were destroyed and all dredges with their machinery sunk to prevent them from falling into Japanese hands. Ores imported into the United States from Netherlands Indies during the latter part of 1941 contained 6,220 tons of tin. The Billiton Co. and the Netherlands Government contracted with the Metals Reserve Co. for the shipment of tin concentrates at the rate of about 2,500 tons (equivalent to 1,875 tons of refined tin) monthly, starting with July. Under the agreement Metals Reserve Co. was to acquire tin concentrates containing 20,000 tons of fine tin to be converted at the Texas City smelter upon the basis of 50 cents per pound, less smelting charges and penalties for impurities.

Nigeria.—Tin mining was greatly accelerated in Nigeria during 1941; consequently, production no doubt reached an all-time peak. The output for the year is estimated at 15,000 long tons of tin. Exports had exceeded 13,200 tons by October; statistics for November

and December are not available. The 5-year contracts between Nigerian producers and English smelters expired during 1941. Owing to the war, new contracts were made for 1 year only at increased rates. The International Tin Committee proposed 15,367 tons as the standard for Nigeria in the new unratified 1942 restriction scheme, with a permissible production quota of 105 percent thereof for the first 6 months of 1942. Estimates indicate a total production of 15,000 tons in 1942. The provisions of the Lend-Lease Act have been made available to mining companies of Nigeria to augment facilities for increasing output. Nigeria is at present the chief source of supply for tin within the British Empire.

Union of South Africa.—The Zaaiplaats Tin Mining Co., Transvaal, which resumed operation of its small reverberatory furnace in 1939, has expanded smelting facilities so as to treat concentrates from Northern Rhodesia, Mozambique, and Swaziland. The output so far has not been large, but during the fiscal year ended July 31, 1941, the company produced 143 long tons of ingot tin compared with 57 tons in the previous year. This establishment operated a smelter during the First World War and sold the metal locally, chiefly to South African railway companies. During recent years, production in the Union of South Africa has averaged 900 tons of concentrates containing 54 percent to 68 percent metallic tin annually.

United Kingdom.—Tin consumption in 1941 amounted to 30,000 long tons compared with 29,225 tons in 1940. Every effort is being made to restrict consumption to 25,000 tons in 1942. Stocks of tin in official warehouses on December 8, the last date information was issued, were 6,517 tons. Deliveries of pig tin during the first 6 months of 1941 amounted to 5,366 tons. Imports of ore from Bolivia and Nigeria apparently were higher than in 1940 and ore receipts for smelting probably were more than adequate to meet requirements. In recent years smelter output has averaged 34,700 tons of tin annually, and doubtless could be greatly expanded as production rose to 55,200 tons in 1929. The Cornwall mines produced 1,600 tons of tin, slightly more than in 1940. As part of a Government drive to increase production of Cornish tin, the Ministry of Supply has agreed to bear all risks and costs necessary to increase output. The tin-mining industry has received "essential works" status so that workers can neither be dismissed nor leave without plausible explanation, and working conditions are guaranteed.

The London tin market has been closed since December 8, 1941. The Government has assumed control of tin prices, industrial stocks, international purchases, and sales. Tin and various alloys containing tin require license for export. Acquisitions of tin, scrap, ore, concentrates, and residues are subject to license. On February 16, 1942, the price of grade A tin, delivered buyers' premises, was fixed at £275 a ton.

U. S. S. R.—Although tin deposits are known in several districts of the Soviet Union, none appears to be capable of extensive development, and only small quantities of tin seem to have been produced there. The Soviet tin demand is therefore accurately measured by its imports, and these indicate a remarkably rapid increase in consumption during recent years. Imports are not available beyond 1937, but information gathered from the trade returns of exporting countries (Netherlands, Great Britain, Belgium, etc.) indicates that

shipments to Russia during 1937 and 1938 averaged 20,650 tons a year. Russia probably entered the war with a substantial reserve stock, but its active buying in August 1941 suggests that tin may have become scarce at that time. Under a barter agreement with China, four Russian credits (since 1938 totaling between $200,000,000 and $250,000,000), with repayment in 5 to 10 years, have been made against shipments of tin and other materials from China to Russia.

An Anglo-Soviet trade pact signed in Moscow on August 16 provided, among other things, for furnishing supplies of tin to Russia by Great Britain. Soon thereafter Russia began buying Straits tin in the East and probably could obtain shipments totaling as much as 9,000 tons. Additional quantities are believed to have been purchased for forward delivery, but it is not known whether British merchants have been able to cover these commitments.

ARSENIC AND BISMUTH

By HERBERT A. FRANKE [1]

SUMMARY OUTLINE

ARSENIC

SUMMARY

Domestic production of white arsenic in 1941 exceeded all previous records and increased 30 percent over that of 1940. Consumption also reached a new peak and exceeded that of 1940 by 28 percent. Demand for white arsenic was so great that producers' stocks neared exhaustion in the fall of 1941. A shortage of arsenic is forecast for 1943 unless production facilities are expanded because of the increased insecticide, military, and other requirements in 1942 and 1943. On May 22, 1942, arsenic was put under allocation control. Quotations on domestic white arsenic advanced from 3½ cents to 4 cents a pound in August 1941.

Salient statistics for arsenic in the United States, 1925–29 (average) and 1938–41

[3] Adjusted for exports by domestic producers.
[4] Complete data not available.
[5] Actual consumption
[6] 10,467 pounds in 1925 and 200 pounds in 1929, no imports from 1926 to 1928, inclusive.
[7] Average for 1928–29, exports of calcium arsenate and lead arsenate not separately recorded by the Department of Commerce prior to 1928.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

World production of new arsenic, which probably set a record, was substantially controlled by the Allies, but because it controlled the output and stocks in Sweden, plus its own production, the Axis had the greatest supplies available.

PRODUCTION

Domestic smelters and refineries operated their roasting and subliming facilities at virtually maximum capacity in 1941 to produce 32,481 short tons of white arsenic. Producers of marketable arsenic included the American Smelting & Refining Co., Anaconda Copper Mining Co., and U. S. Smelting, Refining & Mining Co. which derived their product from baghouse and Cottrell dust, speiss, and accumulated smelter-refinery byproduct residues. Of the production, 83 percent consisted of crude (black) arsenic and 17 percent of refined arsenic.

Crude and refined white arsenic produced and sold by producers in the United States, 1937–41

Year	Crude			Refined			Total		
	Production (short tons)	Sales		Production (short tons)	Sales		Production (short tons)	Sales	
		Short tons	Value [1]		Short tons	Value [1]		Short tons	Value [1]
1937	9,936	10,903	$290,733	6,878	6,733	$250,822	16,814	17,636	$541,555
1938	12,619	9,428	264,004	4,066	3,732	129,018	16,685	13,160	393,022

1941	26,843	28,661	844,793	5,638	6,123	274,527	32,481	34,784	1,119,320

[1] Partly estimated

Production, as reported by the Bureau of Mines, is measured after the low-grade flue dusts containing 20 to 60 percent As_2O_3 are subjected to a roasting or preliminary refining process. This crude arsenic usually contains 93 to 98+ percent As_2O_3. Most of the crude arsenic and a small quantity of better-grade arsenic obtained in certain parts of smelter flue systems are marketed without further refining. Some crude arsenic is refined further. Bureau of Mines statistics on refined arsenic include only products containing 99 percent or more As_2O_3. The arsenic reported as a refined product is not duplicated in the crude arsenic statistics.

It is anticipated that the record 1941 output will be duplicated in 1942. All accumulated arsenic residues in the United States, however, were consumed in 1940 and 1941, and producers will depend largely on current accelerated byproduct recoveries. The American Smelting & Refining Co. has some surplus stock of residue available at San Luis Potosi, Mexico, and is treating it at its El Paso (Tex.) plant. Getchell Mine, Inc., Red House, Nev., installed a Cottrell electrical precipitator unit, two 260- by 7½-foot rotary kilns, and other equipment in 1941 and will become a new producer in 1942, recovering the arsenic by roasting gold ore (which contains arsenopyrite, orpiment, and realgar) before cyanidation.[2] In 1941 the com-

[2] Wise, Fred, Roasting Improves Gold Recovery at Getchell Mine: Min. Cong. Jour., vol. 28, No. 4, April 1942, pp. 48–51.

pany produced a substantial quantity of crude arsenic and made a few small trial shipments of the low-grade material.

Although smelter-refinery facilities have been extended, requirements in 1942 are expected to be much greater than future byproduct production, and it appears that present producing facilities must be substantially expanded. Arsenical ore reserves of the Western States are abundant. In World War I, when a shortage of arsenic developed owing partly to war conditions but mainly to the demand among farmers who had been instructed regarding the merits of arsenical insecticides, several new enterprises were started in the West. A substantial quantity of arsenic was produced from an operation at Gold Hill, Utah. The Jardine Mining Co., Jardine, Mont., which ceased byproduct arsenic production at its gold-mining property in 1936, still possesses its arsenic recovery equipment and has arsenic values in its gold-tungsten ore.

The Anaconda Copper Mining Co. continued to be the sole domestic producer of metallic arsenic in 1941 and increased its output 25 percent over that in 1940. The Rare Metal Products Co., Belleville, N. J., as before, was the only domestic producer of commercial arsenic sulfides.

CONSUMPTION

Data on actual consumption in 1941 were obtained by the Bureau of Mines in a special consumer survey conducted at the request of the War Production Board. Results of the survey are being withheld at the request of the War agencies.

In 1941 calcium arsenate was used chiefly to combat the cotton boll-weevil, leaf-worm, and boll-worm infestations in the South, where the situation became so serious that a local shortage of calcium arsenate developed for a time during the summer. Lead arsenate was employed largely as a spray on apple and pear trees, to exterminate codling and gypsy moths, and to treat soil in the East in destroying the Japanese-beetle grub. The carry-over of calcium and lead arsenate in the hands of suppliers at the end of 1941 was approximately 4,300,000 and 11,250,000 pounds, respectively, compared with about 25,000,000 and 10,000,000 pounds at the close of the 1940 season. Total consumption of calcium and lead arsenate in 1942 is estimated at 45,000,000 and 60,000,000 pounds, respectively. Heavy boll-weevil infestation in the Southeastern Cotton States is predicted where a heavy demand is anticipated for calcium arsenate and molasses as a poison mixture. Other arsenical insecticides were used in 1941 chiefly on truck farms. Federal and State agencies employed considerably less arsenic in fighting grasshoppers, Mormon crickets, and white-fringed beetles in 1941 than in previous years, although Congress appropriated $2,225,000 to the Bureau of Entomology and Plant Quarantine for the control of destructive pests. The Department of Agriculture reports that in 1941 these agencies consumed 210,000 gallons of liquid sodium arsenite for grasshopper bait (75,000 gallons estimated for 1942), 151,000 pounds of calcium arsenate for mole crickets in Florida, and 378,658 pounds of calcium arsenate and 54,232 gallons of liquid sodium arsenite in destroying white-fringed beetles (351,500 pounds and 25,000 gallons estimated for 1942). Sodium fluosilicate largely replaced sodium arsenite to combat grasshoppers

and Mormon crickets and will replace calcium arsenate in fighting the mole cricket in 1942.

There was a tendency in 1941 to substitute arsenic for other poisonous insecticide and rodent constituents because of the difficulty in procuring squill, thallium sulfate, and rotenone (derived from imported derris, cube, and barbasco roots). Loss of the Netherlands Indies and Malaya to Japan cut off a big part of the supply of rotenone-bearing roots, and on April 14, 1942, Conservation Order M-133 limited the use of rotenone poison, which now must come from Latin America. Pyrethrum, however, offers a satisfactory substitute for some insecticidal uses, it is available from Africa, and the flower can be grown in the United States. The use of sodium arsenite as a weed killer rose in 1941 because of the shortage of sodium chlorate and the shift of labor from weed control to more essential work.

Restrictions on the use of tin in cans resulted in the manufacture of more glass containers in 1941, the production of which is expected to greatly increase in 1942 and 1943. Not only does arsenic go into the manufacture of glass containers but also into the making of heat-resisting oven and top-of-stove glassware, electric light bulbs, optical glass lenses, bottles, building, plate, scientific, flat, and other machine and handmade glassware. It is said that the use of arsenic is not absolutely essential as a decolorizer, opacifier, and refining agent for most glass, but the procurement of some substitute materials probably will be difficult. Arsenic consumed by the glass industry in 1941 is estimated to have advanced about 40 percent over that in 1940. Arsenical compounds were used in the treatment of syphilis and other diseases in 1941. There was a marked increase in the sale of arsenic medicinal compounds, chiefly the arsphenamines. A large part of this increased demand went to meet requirements of the armed services, Lend-Lease, and exports. White arsenic was consumed in the manufacture of arsenic acid used in the preparation of insecticides, dyes, and other products. Arsenic wood preservative paste and arsenic in other forms were employed in preserving telephone and fence posts, Celotex cane-fiber insulating board, railroad ties, mine timber, piles, etc. White arsenic and metallic arsenic (made from white arsenic) had limited metallurgical applications in the manufacture of antimonial lead and lead anodes and as a flux or alloying element in copper, brass, white bearing metal, and other alloys. Miscellaneous uses for white arsenic included antifouling paint for ship bottoms (in place of mercury) and the purification of producer gas by the Thylox method.

In view of the tremendously increased insecticide, glass, military, and Lend-Lease requirements, it was considered prudent to begin conserving domestic supplies of arsenic, and on May 22, 1942, it was placed under allocation control by General Preference Order M-152. No producer or distributor of arsenic can make delivery to any person unless he has received specific authorization from the Director of Industry Operations, who controls the quantity of arsenic that a supplier can deliver to any person and the purpose for which it may be used. On July 11, 1942, an amendment to the order covered the procedure by which small consumers could place purchase orders for arsenic. The use of arsenic probably will be greatly restricted in glass, weed killer, and certain insecticides.

On May 18, 1942, the Office of Price Administration issued a maximum price regulation (No. 144) on all household and agricultural insecticides (seasonal commodities). On October 1, 1941, the United States Department of Agriculture revised the Insecticide Act of 1910 providing for proper labeling, declaration of imports, and inspection of insecticides and fungicides.

The Public Health Service reported that manufacturers and distributors sold 18,211,074 doses of arsenical drugs for treatment of syphilis in 1941 compared with only 13,371,490 in 1940. The 5-day arsenic drip method for treatment of incipient cases of syphilis was used in hospitals in Chicago, where an active campaign was waged against venereal disease.

PRICES

Eastern quotations on domestic refined white arsenic, packed in barrels, carlots, rose from 3½ to 4 cents a pound in August 1941. Less than carlot deliveries advanced from 4¼ to 4¾ cents. The actual average selling value for domestic sales in 1941 was only 1.47 cents a pound for crude and 2.24 cents for refined arsenic—an increase of 34 and 52 percent, respectively, over that in 1940. Despite the limited supply of white arsenic, quotations on arsenical compounds were affected only slightly in 1941. Minimum prices for calcium arsenate remained unchanged at 6½ cents a pound during 1941, although there was a slight upward tendency in August, and in February 1942 the price advanced to 7 cents. Some sellers reduced prices on lead arsenate from 9½ cents to 9 cents in January 1941, but later in May and August quotations ranged at higher levels. No quotations were published on arsenic metal, and it is assumed that the nominal price remained at about 75 cents a pound.

Range of quotations on arsenic and its compounds at New York (or delivered in East), 1940–41, in cents per pound [1]

	1940	1941
Arsenic metal, lump, cases	(2)	(2)
White arsenic (As_2O_3), domestic, kegs, carlots	3 00– 3 50	3.50– 4.00
Red arsenic (As_2S_2), imported, cases	17 50–18 00	(2)
Calcium arsenate, wholesale, drums, carlots	6.00– 7 25	6.50– 7 50
Lead arsenate, wholesale, drums, carlots	8 50–11 00	9 00–11.00
Sodium arsenate, wholesale, drums	7 00– 8.00	7 00– 8.00
Sodium arsenite, dry, works, drums: white	8 00– 8.75	7 25– 9.00
Sodium arsenite, dry, works, drums: gray	6 50– 7 50	6 25– 7.50

FOREIGN TRADE

Compared with imports of white arsenic during the first 9 months of 1940 (8,665 tons), imports of white arsenic decreased 13 percent during the 1941 period. Of the 1941 imports, Mexico supplied 88 percent, Canada 9 percent, and Japan 3 percent. Unofficial export data obtained from private sources show that 2,154 tons of white arsenic were shipped abroad in 1941 compared with 1,600 tons in 1940.

Data on the foreign trade in arsenical compounds during the first 9 months of 1941 are given in the table on salient statistics. There was a substantial drop in imports of all arsenical compounds except calcium arsenate, which increased. Metallic arsenic was imported

from the United Kingdom, arsenic sulfide from France, calcium arsenate from Canada, sheep dip from the United Kingdom, and paris green and london purple from the United Kingdom. Exports of calcium and lead arsenate went chiefly to former countries of destination.

White arsenic imported for consumption in the United States, 1937–41, by countries

Country	1937		1938		1939		1940		1941 (Jan.–Sept.)	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

TECHNOLOGIC DEVELOPMENTS

Recovery of arsenious oxide in relatively pure form from metallurgical dusts is claimed by Archibald in United States Patent 2,257,710, which comprises a froth-flotation treatment involving the use of a water and kerosene reagent. Patent 2,257,746 relates to a process for electrolytically oxidizing a water soluble arsenite to the corresponding arsenate, and Patent 2,263,594 concerns the manufacture of cupric meta-arsenite by treating white arsenic and copper with an ammonium chloride solution. By proper control of composition and conditions, iron oxide and tin oxide ores can be dearsenized before reduction begins.[3] A new lead-base bearing alloy developed contains 3 percent arsenic which has, at elevated temperatures, the tensile strength and Brinell hardness equal to tin-base alloys and in general, properties superior to the lead-base and tin-base bearing alloys now in use.[4]

WORLD PRODUCTION AND CONSUMPTION

Tremendous war demands for nonferrous metals in 1941 greatly increased smelter and refinery byproduct production of arsenic. It is not unreasonable to believe that world production of marketable white arsenic exceeded 80,000 tons. Output increased 39 percent in Mexico, 30 percent in the United States, and 11 percent in Brazil, the only countries on which official data are available.

Inasmuch as Sweden is virtually under Axis domination, Germany has available the world's largest source of arsenic—the mines and storage silos of Bolidens Gruv A.-B. The large concrete storage silos at Rönnskar were extended in 1934 to hold 250,000 tons of arsenic, and in 1939 additional storage capacity was added. Germany, France, Greece, Belgium, Italy, Japan, Portugal, and Hungary also are producers of arsenic.

[1] Arsenic is also believed to be produced in Czechoslovakia, Iran, Peru, Turkey, and U. S. S. R. Production figures are not available for these countries.
[2] Data not available.
[3] Data not available. Estimate included in total.
[4] Arsenic content of ores mined is as follows: 1936, 23,312 tons; 1937, 20,954 tons; 1938, 21,480 tons; data not available for later years.

Argentina.—Mexico has replaced Sweden as the source of 1,000 to 1,200 tons of white arsenic required annually for sheep dip and the treatment of hides and skins. In addition, about 9,000 tons of ready-made sheep dip are imported annually.

Brazil.—Of 1,203 metric tons of arsenic produced in 1941, the São João D'el Rey Gold Mining Co. contributed 1,110 tons, Companhia Minas da Passagem 88, and Companhia Brasileira de Mineração 5. The Companhia Minas da Passagem discontinued production during the year. Arsenic may be produced at another property, the São Bento mine. The importation of lead arsenate (for cotton crop) is understood to have been very heavy in 1941.

Bolivia.—Calcium arsenate is expected to be recovered as a by-product in the processing of Bolivian tin ores by the Tainton smelting process.

Canada.—Canadian output of arsenic probably was increased substantially in 1941 by the Deloro Smelting & Refining Co., Ltd., which formerly produced at the rate of about 1,000 tons annually from silver-cobalt-arsenic ores of Cobalt, Ontario. Arsenic residue stock-piled for several years by the O'Brien and Beattie [5] gold mines was marketed, and a contract was let for all future output. Demand reached the point where gold-bearing arsenopyrite ores of the Little Long Lac, Hard Rock, MacLeod-Cockshutt, and other mines in Ontario and Quebec and of the Bralorne and Hedley mines in British Columbia were being considered for their arsenic values.

Chile.—Estimated annual arsenical requirements are 250 tons of lead arsenate, 50 tons of calcium arsenate, and some white arsenic for sheep dip.

[5] Archibald, S. R., Martin, S. J., and Koenen, A. T., Roasting of Beattie Concentrate: Trans. Canadian Inst. Min. and Met., vol. 42, 1939, pp. 608–631.

China.—In 1940 China produced an estimated 800 metric tons of white arsenic and 400 tons of realgar, of which 46.8 tons and 35.7 tons, respectively, were exported.

Mexico.—Arsenic roasting and subliming plants at San Luis Potosi and Torreón operated near peak capacity in 1941. Of 12,590 metric tons of arsenic exported in 1941, 10,101 tons were destined to the United States, 1,706 to the United Kingdom, 532 to Argentina, and 251 to the Union of South Africa.

Peru.—Calcium arsenate was imported from the United States to combat the cotton boll weevil, and some arsenic was received for the preparation of sheep dip. The Cerro de Pasco Copper Corporation has accumulated substantial quantities of arsenical residue and is considering the production of white arsenic.

Spain.—Arsenic and manufactured arsenical compounds, hitherto more economically available from other countries, are being produced in Spain. The Fabrica de Arsenico, Mineras de Arsenico, and the Sociedad Industrias Arsenicales Reunidas are mining and treating mispickel ore from 13 pocket deposits in the northwestern part of Spain. The ore contains 25 to 34 percent arsenic and is mined solely for its arsenic content.[6]

United Kingdom.—Metallic arsenic is marketed by the Metallo Refining Co. Ltd., and it enjoys a steady demand at £325 per long ton. Early in 1942 an association of importer-distributors was formed to handle all sales of foreign white arsenic, which was quoted at £40 per ton, 99+ percent As_2O_3, for lots of 20 tons or over, delivered. Early in 1941 and in the summer of the year quotations for refined white, in warehouse, were only £30 and £33 10s. per ton.

Uruguay.—Annual white arsenic consumption totals approximately 1,000 tons—for cattle and sheep dip, insecticides, and weed killer—which are distributed by the Institute of Industrial Chemistry and Department of Agriculture.

BISMUTH

SUMMARY

Although the Bureau of Mines is not at liberty to publish domestic statistics on production it can be reported that the bismuth output in 1941 surpassed the record output of 1940, largely owing to the treatment of some accumulated rich bismuth residues. Apparent consumption increased about 100 percent over that in 1940. Army and Navy medical units and South American countries increased their purchases of pharmaceuticals containing bismuth, and the aircraft, munitions, machine-tool, building, and other industries consumed much larger quantities of bismuth alloy. Despite the slight increase in production and the doubling of consumption, domestic stocks rose substantially owing to increased receipts of foreign bismuth. During the first 9 months of 1941, imports more than doubled, and exports declined compared with the same period of 1940. The Peruvian Trade Agreement, effective July 29, 1942, halved the import duty on bismuth. Nominal quotations on bismuth remained steady at $1.25 a pound. There was some variance in price of certain bismuth compounds.

[6] Cortell, P., Arsenic in Spain: Ion (Madrid), October 1941; abs. Chem. Trade Jour. (London), vol. 110, February 6, 1942, pp. 145–146.

World production of bismuth totaled an estimated 3,000,000 pounds in 1941, of which the bulk was under control of the Allies.

PRODUCTION

Treatment of some accumulated rich bismuth residues offset an apparent tendency to relax full recovery of bismuth from lead because of the scarcity of magnesium (essential for one lead-debismuthization process) and of the willingness of consumers of lead in their anxiety to secure the metal to tolerate a relatively higher percentage of bismuth, which discouraged maximum refinement. The Anaconda Copper Mining Co., American Smelting & Refining Co., and U. S. Smelting, Refining & Mining Co. continued to be the sole domestic producers. Their production included metal recovered from Mexican lead bullion and from ores imported for smelting and refining from South America, Central America, Australia, and Canada. The Cerro de Pasco Copper Corporation imported large quantities of bismuth and bismuth-lead alloy from Peru to supply the increasing industrial and pharmaceutical demand.

CONSUMPTION

The demand for bismuth doubled in 1941 owing to a great rise in industrial and metallurgical requirements and a slight increase in pharmaceutical applications. It is estimated that 60 percent of the metal was used in pharmaceutical and 40 percent in metallurgical or industrial uses. The industrial demand for bismuth is expected to continue to grow owing to use of the metal as a substitute for tin in solders and to old and new metallurgical uses that the war has greatly expanded. Possibly the industrial or alloy consumption will overtake the pharmaceutical and medicinal use in 1942. Heretofore, as much as 85 to 90 percent of all the bismuth consumed was for medicinal and cosmetic preparations, including various indigestion remedies and toilet powders. Bismuth compounds also are used in treating wounds and venereal diseases, and in 1941 the Army, Navy, and Red Cross reported a substantial growth in demand for bismuth pharmaceuticals.

The Department of Agriculture began experiments in 1941 to replace lead compounds with bismuth subsalicylate in a fungicide spray, which may develop into a sizable use for the metal. The spray is expected to be effective in the treatment of tobacco, potato, and other plant mildew diseases.

The unique characteristics of metallic bismuth—its expansion in passing from the liquid to the solid state, its low melting point, and its nonshrinking properties when alloyed with certain other metals—are responsible for the greatly extended use of the metal in industry and metallurgy. The Cerro de Pasco Copper Corporation, largest supplier of bismuth alloys, has as its principal commercial alloys "Cerrobend" (50 percent Bi.),[7] "Cerrobase" (55.5 percent Bi.), "Cerromatrix" (48 percent Bi.), "Cerrosafe" (42.5 percent Bi.), and "Cerrodent" (38 percent Bi.). In addition, there are several other combinations of bismuth, lead, tin, cadmium, antimony, or mercury containing 33 to 56 percent bismuth. The Federated Metals Division of the American Smelting & Refining Co. began to produce a series of

[7] Curtis, T. M., and Groehn, Harvey G., Cerrobend Tools for National Defense: Modern Industrial Press, November 1941.

How to Bend Tubes and Sections: Iron Age, vol. 146, No. 19, Nov. 7, 1940, pp. 52–53.

new ST solders containing 3 to 5 percent bismuth early in 1942, a use that is expected to become very important. Bismuth reduces the tin required. Furthermore, the new solders have properties comparable with the conventional lead-tin and lead-silver solders. A new wiping solder containing 0.5 percent bismuth and 25 percent tin also was placed on the market, and more bismuth was used in babbitt alloys. Additions of tin and bismuth to lead-silver alloys also constitute a very acceptable substitute for high-tin solders in many instances.[8] The addition of 0.1 to 0.5 percent bismuth in free-machining stainless steels results in a remarkable and useful increase in machinability with no detriment to, and in some cases an improvement in, the corrosion resistance.[9] Bismuth is expected to replace selenium here as the addition agent. Bismuth also is reported to increase the machinability of brasses.[10]

Of the principal metallurgical uses for bismuth during 1941, it is estimated that 24 percent went into the bending of thin-walled aluminum-alloy aircraft oil and gas tubing and steel sections and for trim racks and spotting fixtures in the aircraft and automobile industry; 24 percent into solder and bearing metal; 18 percent into the manufacture of free-cutting aluminum alloys and miscellaneous pattern work; 13 percent into fusible metal for automatic sprinklers, safety valves, and other protective devices; and 21 percent into various other uses such as anchoring bearing bushings on machine tools, sealing of tanks, mounting airplane propellers during machining, setting or anchoring dies, punches, and other parts, and electroforming and electroplating.

PRICES

Throughout 1941 New York quotations on bismuth metal remained unchanged at \$1.25 a pound, tonlots, according to the Engineering and Mining Journal Metal and Mineral Markets. According to the Oil, Paint and Drug Reporter in May 1941 the price of bismuth subcarbonate (fiber drums) decreased from \$1.73 to \$1.50 a pound and bismuth subgallate from \$1.68 to \$1.40 a pound, whereas prices for bismuth subnitrate and subsalycilate remained steady during the year at \$1.48 and \$2.50 a pound, respectively.

FOREIGN TRADE

Imports of bismuth metal during the first 9 months of 1941 (all from Peru) increased 143 percent compared with those received during the same period in 1940 (81,479 pounds). Receipts of compounds, mixtures, and salts of bismuth were insignificant. Imports not valued chiefly for lead during the first 9 months of 1941 totaled 747,757 pounds, of which 400,528 pounds comprised metals other than lead. This classification included shipments from Peru and the United Kingdom. Of the 708,873 pounds from Peru, only 315,785 were lead; probably the remainder was chiefly bismuth. A new trade agreement with Peru, effective July 29, 1942, reduces the import duty on bismuth metal from 7½ to 3¾ percent ad valorem. According to a

[8] Turkus, S., and Smith, A. A., Jr., Low-Tin Solders Containing Silver and Bismuth: Metals and Alloys, vol. 15, No. 3, March 1942, pp. 412–413.

ruling of the Bureau of the Customs, United States Treasury, mixtures of two or more elements, such as lead, bismuth, etc., and bismuth-lead eutectic alloy are dutiable as a combination of chemical elements not specifically provided for at the rate of 25 percent ad valorem.

Bismuth and "compounds, mixtures, and salts of bismuth" imported for consumption in the United States, 1937–41

Year	Bismuth		Compounds, mixtures, and salts of bismuth	
	Pounds	Value	Pounds	Value
1937	67,225	$54,007	3,145	$9,117
1938	92,298	74,583	2,004	3,387
1939	182,832	154,339	297	649
1940	123,880	118,260	4	31
1941 (Jan.–Sept.)	198,162	198,259	15	53

WORLD PRODUCTION AND CONSUMPTION

It is estimated that world production of bismuth in 1941 totaled approximately 3,000,000 pounds, of which the United States, Peru, Mexico, and Canada supplied the greater part. Other producing countries were Bolivia, Spain, Japan, China, Yugoslavia, Sweden, Argentina, Belgium, U. S. S. R., Australia, France, the Union of South Africa, and Germany.

North America.—Mexico produced 215,989 pounds of bismuth in 1941 (408,810 in 1940) and placed an export embargo on bismuth to all countries except the United States and Latin American nations having a satisfactory system of export control. Canadian production of bismuth is not available but is supplied largely by the Consolidated Mining & Smelting Co., Trail, British Columbia, and the Deloro Smelting & Refining Co. Ltd , Deloro, Ontario.

South America.—Production of bismuth in Peru (by the Cerro de Pasco Copper Corporation) in 1941 is reported [11] to have comprised 723,367 pounds of refined bismuth in bars and 422,977 pounds in bars bit refined (bismuth-lead bullion). Output in 1942 is expected to increase substantially over that in 1941. Exports in 1941 totaled 747,369 pounds of metal containing 729,730 pounds of bismuth and 809,096 pounds of bismuth-lead bullion containing 421,083 pounds of bismuth. Bolivia exported 49,833 pounds of bismuth in concentrates in 1941, of which the Compagnie Aramayo de Mines en Bolivio accounted for 15,825 pounds, Fabulosa Consolidated Co. 15,985 pounds, and numerous small operators selling to Banco Minero de Bolivio 18,023 pounds. Production of bismuth in Bolivia could be greatly increased at its tin, tungsten, gold, and bismuth mines but only at considerable cost. Bolivia exported 138,891 pounds of concentrates and ores in 1941 containing 50,706 pounds of bismuth (41,230 in 1940). A plant was established in San Luis, Argentina, in 1941 to recover bismuth metal from the Los Condores scheelite ore. Bismuth was recovered as a byproduct in the São Jose de Brejauva region of Ferros, Minas Gerais, Brazil, in the mining of beryl and aquamarine. From 0.3 to 3.0 percent bismuth occurs in the copper ores of the Pedra Branca region, Paraibo and Rio Grande do Norte, and also in Mariana, Itabirito, and Bomfim, Minas Gerais, and in Iguape, São Paulo.

[11] Foreign Commerce Weekly, vol. 7, No. 1, April 11, 1942, p 20.

Europe.—Unlimited customs licenses were issued in the United States to the British Purchasing Commission in 1941 authorizing the exportation to certain British areas of bismuth metal and alloys; bismuth matte, slimes, and residues; and bismuth salts and compounds. In the United Kingdom bismuth metal was quoted at 6s. 3d. per pound and for 35 percent ore about £110 to £125 per long ton, c.i.f.

Africa, Asia, and Australia.—China produced an estimated 40,000 pounds of bismuth in 1940.

MAGNESIUM

By HERBERT A. FRANKE AND M. E. TROUGHT

SUMMARY OUTLINE

SUMMARY

Events in 1941 forecast that an unprecedented quantity of magnesium would be required for military purposes—for the production of aircraft and incendiary bombs. The War Production Board recommended that magnesium production in the United States be extended more than 90 times that of 1939—to approximately 610,000,000 pounds. In 1941 the production of primary magnesium totaled 32,589,052 pounds—160 percent more than in 1940 (12,521,726 pounds) and 386 percent more than in 1939 (6,700,122 pounds). The 1941 output was greater than the combined output of the previous 4 years. The Dow Chemical Co., an outstanding factor in the magnesium industry since its inception in this country in 1915, was joined by a second producer (for the first time since 1927)—the Permanente Metals Corporation. Dow continued to be by far the principal producer, employing its usual process involving the electrolysis of fused 85-percent magnesium chloride derived from Michigan underground brine and, for the first time, from Texas seawater. Permanente recovered its metal by the new, carbo-electrothermic process, using magnesia from California sea water and Nevada magnesite as its raw materials.

Salient statistics of the magnesium industry in the United States, 1939–41

	1939	1940	1941
Production of primary magnesium.....pounds..	6,700,122	12,521,726	32,589,052
Quoted price per pound [1].....cents..	27.0	27.0	22.5
Imports.....pounds..	76		
Exports.....do....	[2] 4,200,000	1,718,444	[3] 3,098,424
World production (estimated).....short tons..	34,100	49,500	85,500

[1] Lowest nominal price (New York) for primary metal ingot 99.8 percent pure, carlots.
[2] Estimated.
[3] Magnesium metal in primary form, in addition, metal was exported in other forms (86,070 pounds) and in powder (33,383 pounds) during last 6 months of 1941.

Domestic consumption of primary and secondary magnesium in 1941 totaled 29,346,600 pounds compared with 11,531,000 pounds in 1940. Demand for the metal was much greater than the supply, and to meet military requirements mandatory priorities were invoked on magnesium March 3, 1941. Of the primary magnesium shipped or used in 1941, approximately 57 percent went into the production of magnesium-base alloys, virtually all for structural products; 19 percent into other alloys, chiefly aluminum; 6 percent into magnesium products, chiefly nonstructural; 14 percent for export account; and 4 percent into other uses. No magnesium was imported, but more than 3,000,000 pounds were exported. Despite an extraordinary demand for the metal, the market price on 99.8-percent magnesium ingot, carlots, was reduced May 1, 1941, from 27 cents to 22.5 cents a pound.

World magnesium output reached a new peak in 1941, and Germany remained the outstanding producer. Whereas the Axis controlled about 60 percent of the world production during 1941, it is anticipated that in 1942 and 1943 the United Nations will greatly outstrip the Axis in magnesium output.

PRODUCTION

Primary magnesium.—Domestic production of primary magnesium in 1941 totaled 32,589,052 pounds, an advance of 160 percent over the 12,521,726-pound output of 1940. Primary magnesium shipped or used (sales) totaled 31,056,947 pounds. Although the Dow Chemical Co. produced most of the output, the Permanente Metals Corporation contributed a part. Dow placed two entirely new 18,000,000-pound units in operation on the Texas seacoast and expanded annual capacity at its Michigan plant to 18,000,000 pounds. Permanente, the first of 10 new producing companies, started operations in the fall of 1941 with a unit rated at 8,000,000 pounds annual capacity.

Output of the United States is expected to exceed 125,000,000 pounds in 1942 and may reach the goal of 610,000,000 pounds in 1943. The first expansion program announced June 13, 1941, by the Office of Production Management, stated that tremendously increased aircraft and military requirements made it necessary to extend annual productive capacity to approximately 400,000,000 pounds. Soon thereafter, the Dow Chemical Co., Permanente Metals Corporation, Basic Magnesium, Inc., Diamond Magnesium Co., Mathieson Alkali Works, Inc., and International Minerals & Chemicals Corporation (Union Potash) began laying plans for constructing these additional production facilities. By February 1942, however, military needs had risen to a point where a second magnesium-expansion program had to be scheduled, increasing annual capacity to approximately 725,000,000 pounds.[1] This goal was later reduced to 610,000,000 pounds. The following table shows the total projected magnesium program, which, when completed, will make the Government owner of 86 percent of all the domestic magnesium-producing capacity.

[1] Small part British-financed.
[2] Partly Reconstruction Finance Corporation-financed, and capacity expected to be reduced.

The Dow Chemical Co. has developed its process involving electrolysis of fused 85-percent magnesium chloride ($MgCl_2.H_2O$) since 1916. At Midland, Mich., bromine and the sodium and calcium salts in underground brine are first removed by evaporation, filtration, and fractional crystallization; chlorine is added during the process, and the purified magnesium chloride solution remaining is concentrated further by crystallization to yield $MgCl_2.6H_2O$ (hexahydrate). The hexahydrate is partly dried and fed to specially designed, rectangular, cast-steel cells, where the fused magnesium chloride, with some added sodium chloride, is electrolyzed. The metal deposited at the cathode collects on the surface of the electrolyte, from which it is removed at intervals. In addition to high-purity metal, the cell produces byproduct dilute hydrochloric acid and chlorine. Early in 1941 Dow developed an underground brine field near Ludington, Mich., where wells have penetrated magnesium chloride brines richer than those near Midland at a 2,800-foot depth. This brine, containing about 10 percent $MgCl_2$, will be concentrated and shipped to Marysville, Mich., where it will be enriched with dolomite, converted to hexahydrate, and treated electrolytically. Some of the Ludington brine was shipped by railroad tank cars to Midland during the first part of 1942. At Freeport and Velasco, Tex., Dow adds milk of lime to sea water and precipitates magnesium hydroxide, which is thickened, filtered, and treated with hydrochloric acid to produce

$MgCl_2.6H_2O$.[2] This is made almost anhydrous and electrolyzed in the same manner as at Midland. In the interest of the war effort, the Dow Chemical Co. offered (through the Office of Production Management and the Defense Plant Corporation) its process and technique to the Diamond Alkali Corporation and the International Minerals & Chemicals Corporation. The Dow Magnesium Corporation was formed to operate the Velasco and Marysville plants for the Defense Plant Corporation.

The Mathieson Alkali Works, Inc., developed jointly with the staff of the Consolidated Mining & Smelting Co. (Trail, B. C.) a special type of electrolytic cell which is reported to be advantageous at present in that almost 3 pounds of concentrated chlorine gas are produced for each pound of magnesium metal made and a slight saving in electric current is indicated. Mathieson will treat waste calcium chloride solution from its Solvay process with calcined dolomite and carbon dioxide to produce magnesium chloride solution and byproduct calcium carbonate. The calcium carbonate precipitate is filtered off and the magnesium chloride solution purified, evaporated, and dehydrated enough for electrolysis. The operation makes possible the economic disposal of huge quantities of calcium chloride resulting from the ammonia-soda process for sodium carbonate production and the use of low-cost dolomite.

The Diamond Magnesium Co. not only takes advantage of the fact that dolomite, a double carbonate of lime and magnesia, can supply the lime needed for its Solvay ammonia-soda process but, in conjunction with some of the process waste liquors, the magnesia yields a cheap magnesium chloride. Some of Diamond's cell feed will be derived from waste liquors, and some will be produced by direct treatment of calcined dolomite with hydrochloric acid. Hydrated dolomite will be treated with the chloride waste liquors to produce magnesium hydroxide and calcium chloride, which will be carbonated with kiln gases. The calcium carbonate is precipitated and the magnesium chloride obtained is made almost anhydrous. The regular Dow type of cell will be employed in the electrolysis.

Magnesium will be produced by the International Minerals & Chemicals Corporation (at Austin, Tex.) primarily from magnesium chloride derived as a byproduct in the base exchange of langbeinite ($K_2SO_4.2MgSO_4$) and sylvite (KCl) solutions (which average about 17 percent $MgCl_2$) in the production of sulfate of potash by its subsidiary, the Union Potash & Chemical Co., at Carlsbad, N. Mex. Part of the cell feed, however, will be derived from hydrated dolomite, carbonated with kiln gases, and treated with hydrochloric acid produced as a byproduct from the Dow-type electrolytic cell. Heretofore the company wasted substantial quantities of the magnesium chloride solution at Carlsbad.

Basic Magnesium, Inc., will employ another magnesium chloride electrolytic process, which differs from that of Dow's primarily in that it employs a completely anhydrous feed instead of an almost anhydrous magnesium chloride. The so-called M. E. L. method was developed in Germany by I. G. Farbenindustrie, A. G., and later

was used by Magnesium Elektron, Ltd., at Clifton Junction, England, after which the Nevada plant is modeled. A tremendous quantity of magnesite must be quarried and concentrated by flotation for this huge plant. Plans are to quarry the magnesite[3] and transport the beneficiated raw material from Gabbs, Nye County, northeast of Luning, Nev., to Las Vegas, over 300 miles away. Raw magnesite and magnesium oxide sinter (from Herreshoff roasters) will be ground and briquetted with coke and British Columbia peat moss to make a spongy, porous mass, which will be roasted and treated with chlorine gas to produce anhydrous magnesium chloride. The chlorine gas will be derived partly from gases evolved from the magnesium cells and partly from the electrolysis of sodium chloride.

The Permanente Metals Corporation will employ two different processes to produce magnesium—the direct carbo-electrothermic and the ferrosilicon reduction methods. Development of the carbothermal process has been largely credited to Fritz J. Hansgirg, an Austrian scientist, who designed and installed the initial unit at Permanente, Calif.[4] The method involves many difficult problems, primarily because it is based upon a chemical reaction easily reversible and requires the maintenance of a reducing or inert environment throughout to prevent reoxidation. Operations of the plant have been retarded by explosions and fires resulting from the difficulties of controlling temperatures and vacuums, which is so highly essential. Briefly, the Hansgirg process consists in mixing coke and calcined magnesia and heating the mixture in an electric arc furnace at about 2,100° C. and then suddenly "shock-cooling" the resultant vaporized metal at about 200° C. with natural gas. The finely divided magnesium or powder, separated from the gas by Cottrell precipitators, is contaminated with carbon, magnesium oxide, and other impurities and must be redistilled. It is mixed with oil and the doughy mixture redistilled in special furnaces, the oil and then the magnesium being vaporized. High-purity magnesium crystals are recovered from the top of the furnace. In 1941 Permanente employed magnesium oxide obtained from sea water and Nevada magnesite by the Westvaco Chlorine Products Co. at Newark, Calif., as its raw material. Early in 1942 the company abandoned its original plan to rely upon Nevada magnesite and began constructing its own sea-water magnesia plant at Moss Landing, Calif. By the summer of 1942, two carbothermal units had been completed, but neither unit had yet approached its rated capacity.

The ferrosilicon process was largely adopted for the second magnesium expansion program. Work thereon was pioneered by Dr. L. M. Pidgeon of the Canadian National Research Council,[5] the Ford Motor Co., and the Electro Metallurgical Co. Its adoption was recommended by the National Academy of Sciences The process involves briquetting high-grade dead-burned dolomite and pulverized ferrosilicon (75-percent grade) and heating in a horizontal or vertical furnace or some other form of retort equipped with a condenser unit.

[4] Kirkpatrick, Sidney D., Magnesium by the Hansgirg Process: Chem. and Met. Eng., vol. 48, No. 9, September 1941, pp. 91–94.

[5] Breyer, Frank A., Pidgeon Ferrosilicon Process for Magnesium: Chem. and Met. Eng., vol. 49, No. 4, April 1942, p. 87.

Killeffer, D. H., Magnesium from Dolomite by Ferrosilicon Reduction: Chem. and Eng. News, vol. 20, No. 6, March 25, 1942, p. 369.

Reduction takes place under high vacuum at about 1,150° C., and the vaporized magnesium is condensed as a metal of high purity in the water-cooled section of the retort. Any fuel (such as gas, oil, or electricity) that will give uniform heat at constant temperature can be used. It is reported that a pressure of less than one-tenth millimeter should be maintained in the furnace. The charge is heated with the particular equipment selected long enough to vaporize most of the magnesium in the dolomite. Residue remaining in the retort after heating consists chiefly of dicalcium silicate, calcium oxide, and some magnesium oxide and ferrosilicon. Approximately 1 pound of ferrosilicon and 12 pounds of dolomite are required to produce 1 pound of magnesium metal. Attention was drawn to the process because it requires a minimum of electric power (chiefly that used in production of ferrosilicon), it utilizes dolomite (which is very abundant), and a plant can be erected in a relatively short time. The process, however, necessitates substantial expansion of ferrosilicon production capacity and the use of a large quantity of critical nichrome steel for manufacture of the retorts.

The Ford Motor Co., Electro Metallurgical Co., Permanente Metals Corporation, New England Lime Co., Amco Magnesium Co. (American Metals Co.), and National Lead Co. will construct magnesium plants using the ferrosilicon process; some of them will start operation by the summer or early fall of 1942. Ferrosilicon will be supplied by other concerns, except for the Electro Metallurgical Co., which is constructing its own 48,000,000-pound ferrosilicon plant near Spokane.

Dolomite [6] for the various magnesium plants probably will be obtained by Ford and Dow from Ohio and Michigan, by Mathieson from Burnet County, Tex., by Permanente from deposits near Salinas, Monterey County, Calif., and by the other companies from deposits relatively near their plants.

Other companies, raw materials,[7] and processes [8] were considered in connection with the production of magnesium, but the program to date has not permitted their inclusion. Olivine, dunite, and serpentine have been considered as raw materials for the production of magnesium, and processes receiving attention have included ferrosilicon, thermal, and hydrochloric acid processes.[9] The Defense Plant Corporation allocated funds for drilling and testing carnallite-sylvite beds in the vicinity of Thompsons, Grand County, Utah (in connection with Utah Magnesium Corporation) and of magnesium chloride brines near Gail, Borden County, Tex. (by Ozark Chemical Co.). The Geological Survey and Bureau of Mines cooperated in these drilling programs, as well as in the investigation of magnesite, dolomite, brucite, brines, and other magnesium-bearing raw materials, particularly in the western United States.

The Aluminum Co. of America, American Magnesium Corporation, Magnesium Development Corporation, Dow Chemical Co., General Aniline & Film Corporation, and I. G. Farbenindustrie, A. G., were indicted by the Department of Justice on January 30, 1941, for violation of the Sherman Antitrust Law. Charges stated that these companies had retarded and stifled production by pooling patents, maintaining high prices, limiting consumers to one domestic source of supply, and making unlawful agreements pertaining to foreign sales and output in the United States. On April 15, 1942, the first five companies filed a plea of nolo contendere (no consent), and a consent decree was entered that provides for compulsory and free licensing of patents held by the defendants for producing and fabricating magnesium during the war. The concerns and individuals contended that this action was taken to settle the case at any cost as quickly as possible so that time (more important for the production and fabrication of aluminum and magnesium) could be devoted entirely to defeat of the Axis and that actually none was conscious of wrongdoing. Fines imposed aggregated $110,000 for the corporation defendants and $30,000 for the individuals. The half interest owned by the General Aniline & Film Corporation in the American Magnesium Corporation was purchased by the Aluminum Co. of America on February 6, 1941, when a huge magnesium-fabrication expansion program also was inaugurated.

Production and fabrication of magnesium were threatened by short-lived strikes of the Die Casting Workers (C. I. O.) at the Cleveland plant of the American Magnesium Corporation in April 1941 and by the Gas, Coke, and Chemical Division of the United Mine Workers (C. I. O.) at the Midland plant of the Dow Chemical Co. in June 1941.

Explosions and fires damaged magnesium plants of the Permanente Metals Corporation (ingot), National Magnesium Corporation (powder), and Wellman Bronze & Aluminum Co. (castings) during 1941.

Old and new companies that expanded or began to fabricate magnesium products during 1941 and the first half of 1942 through the Defense Plant Corporation were: American Radiator & Standard Sanitary Corporation, at Louisville, Ky., and Elyria, Ohio—sand castings for aircraft engines and wheels; Bendix Aviation Corporation, at Bendix, N. J.—castings (1,920,000 pounds annually); Dow Magnesium Corporation, at Bay City, Mich.—sand castings (700,000 to 900,000 pounds monthly); Ferro Enameling Corporation, at Bedford, Ohio—powder (200,000 pounds monthly); Hills-McCanna Co., at Chicago, Ill.—sand castings (30,000 pounds monthly); Howard Foundry Co., Inc., at Chicago, Ill.—sand castings; Revere Copper & Brass, Inc., at Rome, N. Y.—forgings; and Wellman Bronze & Aluminum Co., at Cleveland, Ohio—castings.

Secondary magnesium.—Recovery of secondary magnesium totaled 1,752 short tons in 1941 and required the consumption of 2,279 tons of magnesium scrap, which was almost entirely new scrap. Of the quantity of magnesium recovered, 929 tons were as ingot and 738 went into castings, 60 into aluminum alloys, and 25 into chemical reagents. During the first part of 1942, six companies had been authorized to remelt scrap and produce secondary magnesium: Aluminum & Magnesium, Inc., American Magnesium Corporation, Apex Smelting Co., Dow Chemical Co., Federated Metals Division of

American Smelting & Refining Co., and National Smelting Co. Additional information on secondary magnesium will be found in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

After magnesium was placed under mandatory priority control, virtually all of the metal was consumed for military purposes, for the production of airplanes and incendiary bombs. Apparent primary consumption exceeded that in 1940 by 151 percent. Of the primary magnesium shipped or used in 1941 (31,056,947 pounds), approximately 57 percent was used in the production of magnesium-base alloys, virtually all for structural products; 19 percent in other alloys, chiefly aluminum; 6 percent in magnesium products, chiefly nonstructural; 14 percent for export account; and 4 percent in other uses.

As magnesium oxidizes readily at temperatures above the melting point, approximately 27 percent of the metal consumed in the production of magnesium-base alloys and the manufacture of structural products was lost or burned in processing.

Production, sales, imports, exports, and apparent consumption of primary magnesium in the United States, 1939–41, in pounds

Year	Production	Sales	Imports	Exports	Apparent consumption[1]
1939	6,700,122	10,650,121	[2] 76	[3] 4,200,000	6,450,200
1940	12,521,726	12,823,633	....	[4] 1,668,765	11,154,868
1941	32,589,052	31,056,947	....	3,098,424	27,958,523

[1] Does not consider fluctuations in consumers' stocks and metal derived from scrap. Withdrawals from producers' stocks totaled 3,949,999 pounds in 1939 and 301,907 pounds in 1940, additions to producers' stocks totaled 1,447,615 in 1941.
[2] Includes alloys and scrap (magnesium content).
[3] Estimated.
[4] Of the 1,718,444 pounds of metal exported, 49,679 pounds consisted of magnesium alloy.

Actual consumption of magnesium (from primary and secondary sources) totaled 29,346,600 pounds. Of this, 75 percent was used in the manufacture of magnesium-base alloy structural products, 23 percent in aluminum alloys, and 2 percent in other uses.

Actual domestic consumption of primary and secondary magnesium (magnesium content), 1940–41, by uses, in pounds

Use	1940	1941
Structural products[1]	7,363,200	21,951,900
Aluminum alloys	3,556,500	6,762,200
Other alloys	85,600	59,000
Scavenger and deoxidizer	361,600	130,400
Pyrotechnics	43,500	383,200
Chemicals	70,200	27,600
Other	50,400	32,300
Total	11,531,000	29,346,600

[1] Castings, sheet, extruded shapes, forgings, etc.

Magnesium-alloy structural products manufactured and sold or used in the United States increased 150 percent over those of 1940. The manufacture of nonstructural products advanced 84 percent. Of the structural products sold or used, sand and permanent mold cast-

ings comprised 87 percent, die castings 6 percent, extruded products 3 percent, sheet 3 percent, and other structural products 1 percent. Of the nonstructural products, powder comprised 68 percent, stick 28 percent, and shavings, turnings, wire, ribbon, and other products 4 percent. The value of sand and permanent mold castings manufactured in 1941 averaged \$2.07 a pound, die castings \$1.50 a pound, and all castings \$2.03 a pound (compared with \$1.71 in 1940).

Magnesium products (other than ingot) manufactured in the United States and sold or used by the companies manufacturing the products, 1939–41

[1] Not available. [2] Revised figures.

Of the magnesium-alloy structural products sold or used, the aircraft industry took 96 percent and incendiary bomb casings and other industries, 4 percent. Of that going into the aircraft industry, 61 percent was for the manufacture of engines (including propellers), 22 percent for wheels, 10 percent for frames, and 7 percent for aircraft accessories. Sand, die, and permanent mold castings comprised 95 percent of all the magnesium-alloy structural products sold or used in the aviation field.

Consumption of magnesium-base alloy structural products in 1941, by uses

Use	Pounds	Use	Pounds
Aircraft:		Portable machine equipment and tools	146,427
Engine	7,943,998	Textiles	90,811
Frame	1,358,988	Foundry equipment	55,097
Wheel	2,878,833	Oil-field equipment	2,395
Accessories	885,666	Printing	8,293
Incendiary bomb casings	15,116	Other industries	62,143
Automotive	181,972		
Stationary machines	45,594	Total	13,675,333

Fabricators of magnesium structural products increased from 30 in 1940 to 38 in 1941 and of nonstructural products from 4 to 6. By the end of 1941, 24 companies were producing sand castings, 2 per-

manent mold castings, 10 die castings, 2 extruded products, 2 forgings, and 5 powder. The largest producers of alloy structural products were the American Magnesium Corporation, Dow Chemical Co., Wright Aeronautical Corporation, Bohn Aluminum & Brass Corporation, Eclipse Aviation Co. (subsidiary of Bendix Aviation Corporation), Springfield Bronze & Aluminum Co., Doehler Die Casting Co., Harvill Aircraft Corporation, Hills-McCanna Co., Magnesium Products Corporation, and Ford Motor Co. Producers of powder included American Magnesium Corporation, Magna Manufacturing Co., Magnesium Corporation of America, National Magnesium Co., and National Metals Co.

Stocks of primary magnesium materials on hand at producers' and consumers' plants December 31, 1941, totaled 6,092,699 pounds, including 3,312,179 pounds of primary and 2,780,520 pounds of alloy ingot. Stocks of secondary materials totaled 293,995 pounds.

NATIONAL DEFENSE AND WAR MEASURES

As the demand for magnesium became greater than the supply, production of the metal was placed under mandatory priority status by the Office of Production Management on March 3, 1941. Preceding this action, on February 12, 1941, the Director of Priorities had directed that all manufacturers and fabricators of magnesium give preferential consideration to defense projects. General Preference Order M-2 was issued March 24, 1941. All defense orders for magnesium were thereby assigned a preference rating of A-10 or better. A statement of March 26 stipulated that defense orders for Great Britain were to receive the same priority treatment as those of the United States. On November 14, 1941, General Preference Order M-2-b was issued, conserving the supply and directing the distribution of magnesium, which prohibited its contamination and debasement; allocated the output of producers, approved smelters and fabricators; confined all purchase orders to uses bearing a rating of A-1-j or higher; made inventory and scheduling provisions, and provided for the collection, segregation, and disposition of scrap.

As the need for aircraft and incendiary bombs multiplied, the magnesium-production program was increased by the Office of Production Management, first on June 13, 1941, from a previously contemplated 75,000,000 pounds to 400,000,000 pounds annually. Six domestic companies became identified with this first magnesium-expansion program—Dow, Permanente, Basic Magnesium, Diamond, Mathieson, and International Minerals (Union Potash). As war and lend-lease requirements rose, the War Production Board announced the second expansion program (on February 26, 1942) extending capacity to approximately 610,000,000 pounds. Five additional companies were added to the six previously named concerns—Ford, Electro Metallurgical, New England Lime, American Metals, and National Lead.

PRICES

Dow's price for 99.8-percent standard four-notch ingots (17 pounds) of magnesium, carlots (30,000 pounds minimum), was reduced from 27 cents to 22.5 cents a pound on May 1, 1941. For less than carlots, 100 pounds or more, the price was dropped from 29 cents to 24½

cents. Quotations for 4-inch-diameter by 16-inch ingots (12 pounds) and six-notch ingots (6 pounds), carlots, were reduced to 23.5 cents and for extruded sticks to 32 cents. The new price quoted on magnesium alloys (except Dowmetal "M" and "R-1"), in carlots, standard four-notch ingots (21 pounds), was 24.5 cents a pound, and on the standard 3-pound die-casting ingot, 25.5 cents. All quotations were f. o. b. producing plant, with freight allowed on 100 pounds or more to all points in the United States. On January 1, 1942, the above quotations on magnesium alloys were increased ½ cent a pound. Magnesium-ingot quotations in London remained stationary at 1s. 6d. a pound during 1941.

FOREIGN TRADE

No magnesium was imported in 1941. Exports of magnesium metal in primary form in 1941 totaled 3,098,424 pounds valued at $860,486, of which 2,313,227 pounds went to the United Kingdom, 656,420 to Canada, 64,771 to Australia, 40,000 to Argentina, 20,000 to Mexico, 2,340 to China, and 1,666 to various other countries. In 1940 exports totaled 1,718,444 pounds valued at $582,961. Official records on exports of the metal in other forms (available only for the last 6 months of 1941) totaled 86,070 pounds valued at $29,620, of which 58,398 pounds were consigned to the United Kingdom and 25,116 to Canada. Exports of magnesium powder from July 1 to December 31, 1941, totaled 33,383 pounds valued at $14,797, of which 26,575 pounds were sent to the United Kingdom and 6,500 to Canada. The metal has been under export control since November 5, 1940.

TECHNOLOGIC DEVELOPMENTS

Mass production of magnesium resulted in new methods for recovering the metal from various raw materials and the development of improved fabricating technique. Most of the new magnesium processes have already been discussed in this chapter under "Production." The Bureau of Mines investigated three new magnesium processes believed to have merit—the direct electrothermic method involving carbon reduction of magnesium oxide and condensation by an oil spray, use of molten lead to condense electrothermic magnesium vapor and subsequent electrolysis of the lead, and direct reduction of magnesium oxide in an electrolytic cell. Operation of a pilot plant at Pullman, Wash., revealed that a light stove oil is as effective as gas for shock-cooling magnesium vapor when atomized in a nozzle of proper design.[10] Further work is planned on the two-stage continuous distillation of the oil sludge formed in the electrothermic process.

Radically new fabrication methods were placed in operation by the manufacturers of magnesium powder, of which there were over 10 in June 1942. Mounting aircraft requirements prompted the construction of large, new, streamlined magnesium-alloy sand-casting foundries. Among the up-to-date melting, casting, and heat-treating installations are those of Ford, Wright Aeronautical, American Magnesium, Dow, Bohn, Magnesium Products, Hills-McCanna,

[10] Doerner, H. A., Holbrook, W. Floyd, Dilling, E. Don, Harris, Dwight L., Magnesium by Electrothermic Reduction. Bureau of Mines Rept. of Investigations 3635, 1942, 47 pp.

Aluminum Industries, Light Metals, Superior Bearing Bronze, Eclipse Aviation, Wellman Bronze & Aluminum, and Springfield Bronze & Aluminum.[11] Advancements also were made in the manufacture of permanent and semipermanent mold castings and of die castings, sheet, strip, plate, extruded shapes, and forgings. Companies that formerly fabricated other metals started manufacturing magnesium-alloy products in 1941 and early 1942. Dow and American Magnesium remained the only producers of sheet.

Preliminary static tests were completed on a magnesium-alloy airplane wing to determine its possible weight saving and general suitability for aircraft construction.[12] Progress was made in 1941 on methods for combatting corrosion of magnesium.[13] Numerous patents were issued on improved methods for producing, treating, and protecting magnesium and its alloys. Studies were made on the extinguishment and control of magnesium and incendiary-bomb fires.[14] Care of atmospheres and heat-treating methods for magnesium products became increasingly important.[15] Demand increased during 1941 for high-purity magnesium alloys in which the iron, nickel, and copper impurities were removed—Dow metal J-1, for extrusions, sheet, and forgings; O-1, for extrusions and forgings; and FS-1, for sheet and extrusions. These new alloys have high corrosion resistance.

WORLD PRODUCTION

World production and consumption of magnesium in 1941 set a record. Most of the metal found its way into the manufacture of airplanes and incendiary bombs. Of the world output, it is estimated that about 60 percent was under Axis control and 40 percent under control of the Allied Nations.

Estimated world production of magnesium, 1937–41, by countries, in metric tons

Country	1937	1938	1939	1940	1941
Australia					200
France	1,500	1,800	2,500	2,000	3,000
Germany	12,080	14,100	16,500	25,000	35,000
Italy	66	102	300	500	2,500
Japan	1,200	1,500	2,000	3,000	5,000
Norway					100
Switzerland	230	750	750	750	1,000
U. S. S. R.	500	500	1,000	1,500	4,000
United Kingdom	2,000	2,200	4,831	6,500	12,000
United States	[1] 2,059	2,918	3,039	5,680	14,780
Total	19,600	23,900	30,900	44,900	77,600

Australia.—Production at a 1,000-ton magnesium plant was begun in the summer of 1941 by the Broken Hill Proprietary Co., Ltd., at New Castle, New South Wales. Finely ground calcium carbide and calcined magnesite are heated under vacuum, and the metal obtained is remelted and refined with suitable fluxes.[16]

Canada.—Dominion Magnesium, Ltd., early in 1942 began constructing a 3,500-ton magnesium plant at Haley near Renfrew, Ontario, based upon the dolomite-ferrosilicon process developed by Dr. L. M. Pidgeon of the Canadian National Research Council. The project is sponsored by Bobjo Mines, Ltd., Moneti Associates, and Ventures, Ltd., but cost of the plant ($3,000,000) is to be borne by the Canadian Government. The Consolidated Mining & Smelting Co. of Canada, Ltd., is reported planning construction of a 5,000-ton magnesium plant in eastern Canada. It was first planned to locate this plant in western Canada, near the newly developed Marysville magnesite ore belt (4½ miles long) north of Cranbrook, B. C. At Trail, B. C., this company produced magnesium powder by a new atomization method. At Farm Point near Wakefield, Quebec, the Aluminum Co. of Canada, Ltd., started production of pure granular magnesia suitable for both refractories and the manufacture of magnesium metal from brucitic limestone. Virtually all of the current output, however, is to be used for refractory brick.[17] The British Columbia Magnesium Co., Ltd. (one of several concerns planning the production of magnesium in Canada) began exploratory work in 1941 on magnesite deposits in the Williams Lake and Clinton districts, B. C., of which some ore contains 40 percent MgO and 27 percent Cr_2O_3.

France.—Several leading chemical companies (Pechiney, Ugine, and Bozel-Maletra) plan to increase French production of magnesium. Dolomite and Mediterranean sea-water brine apparently constitute the principal raw materials used. A new plant at Lannemazon in the Pyrenees is expected to be completed early in 1942. Magnesium plants formerly reported in operation are located at Saint-Auban, Jarrie-Vizille, Villard de Bozel, and Moissac.

Germany.—German production of magnesium may have reached 50,000 tons in 1941, as production capacity is believed to have totaled that amount in 1940. Plants operated by the I. G. Farbenindustrie, A. G., were located at Bitterfeld (employing a process similar to Dow's with potash end liquor and magnesite), at Aken near Dessau (Magnesium Elektron process), and at Wintershalle; and by the Wintershall A. G. (the potash combine) at Wintershalle and Heringen (employing an electrolytic process with carnallite). Two new plants in central Germany and the rebuilt Radenthein (Austria) plant probably were in operation also. German interests were expected to complete construction of a 10,000-ton magnesium plant in Norway in 1941 based upon sea water and potentially available hydroelectric power.

Italy.—Italian magnesium production has been estimated in 1941 at 800 to 3,000 tons. The Fraschini automobile and Montecatini chemical interests are producingm agnesium from dolomite in northern

[16] Chemical Engineering and Mining Review, Magnesium Manufacture in Australia Vol. 34, No. 400, January 10, 1942, pp. 121-126.

ern Italy, and Montecatini is recovering magnesium from sea water on the Ligurian coast.

Japan.—Magnesium production is believed to have been greatly increased in 1941, and 15 companies (which the Government was attempting to consolidate) are said to have been established early in the year. Probably the five best-established and largest producers were the Nichiman (Japan-Manchuria) Magnesium Co., Ltd. (at Ube, Yamaguchi Prefecture—2,000 tons capacity); Japan Magnesium Metal Co., Ltd. (at Konan, South Kanyo Province, Chosen—2,000 tons); Asahi Electro-Chemical Industry Co., Ltd. (at Tokyo—560 tons); Japan Soda Co., Ltd. (at Toyama—360 tons); and Manchurian Magnesium Manufacturing Co. (at Yinkow, Manchuria—3,000 tons). Adequate supplies of raw material are available to Japan from the immense magnesite reserves at Tashihchiao and on the Liao-Tung Peninsula in Manchuria and in Chosen, and from the sea-water bitterns of the Gulf of Liao Tung and the Inland Sea.

United Kingdom.—Magnesium Elektron, Ltd., and Magnesium Metals & Alloys, Ltd., are estimated to have produced about 12,000 tons of metal in 1941 and are expected to double that amount in 1942. Domestic dolomite, sea water, Greek magnesite, and magnesite from West and South Africa are used as raw materials.

ANTIMONY

By T. H. Miller and A. L. Ransome [1]

SUMMARY OUTLINE

SUMMARY

Under the impetus of rising demand, the antimony industry made general over-all gains during 1941. Although imports from China advanced over those in 1940, a continued shortage of Chinese metal stimulated domestic consumers of antimony to look to increased Mexican and South American ore supplies, which were augmented by a larger domestic production. World production is estimated to have been 55 percent greater than the 1938 total of 32,000 metric tons, based upon comparative gains from countries that produced 57 percent of the 1938 total.

High prices resulted from the increased competition, and 50- to 55-percent ores quoted at \$1.25 to \$1.35 a short-ton unit, New York, at the beginning of 1941 were priced at \$2.00 to \$2.10 at the close of the year. Despite the sharp rise in ore prices, the quotation for domestic metal remained at 14.00 cents a pound, New York, the same as in 1940. Quotations for Chinese metal were nominal at 16.50 cents, duty paid, throughout the year, a continuation of the 1940 price.

Domestic production of antimony ore and concentrate advanced 208 percent over 1940, but metal content rose only 146 percent, an indicated average drop in grade from 44 percent in 1940 to 35 percent in 1941. The antimony content of antimonial lead produced from all classes of domestic and foreign ores increased 42 percent over the 1940 figure and was the largest recorded since 1929. The content of the total production of antimonial lead at primary refineries from all raw materials—scrap and domestic and foreign ores—increased 19 percent and was the largest since 1929. Primary antimony available for consumption increased 67 percent to the highest point reached in many years. Stocks of metallic antimony at producers' plants, as reported to the Bureau of Mines, decreased from 1,048 short tons at the end of 1940 to 730 tons on December 31, 1941. The Laredo (Tex.) smelter and Kellogg (Idaho) electrolytic plant both reported marked increases in

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce

production that greatly exceeded a drop in output from the Los Angeles smelter. The new electrolytic plant of the Sunshine Mining Co., under construction, should contribute to increased total production in 1942.

Figure 1 shows trends in world production from 1910 to 1938 and United States imports and prices from 1910 to 1941.

NATIONAL DEFENSE

The strategic aspects of antimony are based upon the dependence of the United States on imported ores and metal to supply the demand for which domestic production can fill only a minor, but increasing, percentage. The dislocation of the Chinese antimony industry since

1937 has led to substantial changes in world antimony industry, which have tended to reduce the dependence of this country, among other democracies, on Chinese supplies. The decline in Chinese exports has been more than offset by the expansion in production, with American financial aid, in Mexico and Bolivia, of which virtually the whole supply is available to the United States. Notwithstanding this potential supply, antimony was comparatively scarce throughout 1941, but no mandatory priorities were invoked during the year by the Office of Production Management, even though some metal was withdrawn from Government stock piles to relieve shortages. On September 13, 1941, the Metals Reserve Co. announced that 7,014 tons of Chinese and 1,250 tons of domestic metal had been delivered to its stock pile, and 19,623 tons of foreign and 1,750 tons of domestic antimony were on order.

On August 21, 1941, American antimony prices advanced 0.50 cent a pound to 14.50 cents, New York—the first price change recorded since September 23, 1939. This rise was short-lived, however, as the Office of Price Administration and Civilian Supply on August 22 requested that the 14.00-cent level be maintained; it remained at that point until March 23, 1942, when the Office of Price Administration allowed the price advance to 15.96 cents for small case lots.

On March 30, 1942, allocation control over antimony was ordered by the Director of Industry Operation of the War Production Board, with issuance of General Preference Order M-112, effective May 1. Under this order, deliveries of antimony were strictly controlled. Subsequently, on July 11, 1942, order M-112 was amended to allow up to 50 tons a month of contained antimony in ore or concentrates to be delivered by producers without restriction.

DOMESTIC PRODUCTION

MINE OUTPUT

The extent of the increased activity as regards antimony in 1941 is not apparent from the record of production of antimony ores and concentrates alone. The number of producing mines and prospects has nearly doubled, as is indicated by the fact that 37 properties contributed to the country's total production of antimony ores in 1941 compared with 19 in 1939. In addition, much development work in the past year or two has not yet resulted in production. Moreoever, mines containing ores that are produced principally for their values in metals other than antimony have supplied increasing quantities of this metal for domestic consumption. The augmented supplies of antimony from ores containing values mainly in silver, copper, and other metals were available partly as the result of operation of the new Bunker Hill & Sullivan Mining & Concentrating Co. plant at Kellogg, Idaho.

There were 3,460 tons of material, containing 1,214 tons of antimony, classed as antimony ores and concentrates produced in 1941 compared with 1,124 tons of material containing 494 tons of antimony in 1940. Upon the basis of antimony content, the record for 1941 was surpassed in only 3 previous years—1915, 1916, and 1937. Shipments totaled 2,834 tons containing 1,018 tons of antimony in 1941 compared with 1,108 tons containing 490 tons in 1940.

497779—43——50

The development of new large reserves of low-grade antimony ore by the Bureau of Mines at the Yellow Pine mine, discussed briefly under Idaho, and the availability of markets in Los Angeles and Laredo, among others, for small as well as large lots of domestic ores, foretell a substantial increase in output of antimony from domestic mines, should a prolonged war require. The new Bunker Hill plant at Kellogg and the prospective Sunshine Mining Co. plant at Big Creek near Kellogg indicate that larger quantities of antimony will be available from domestic silver, copper, and other ores not classed as antimony ores.

Alaska.—Shipment of antimony ores from Alaska in 1941 was again confined to the Stampede mine of Morris P. Kirk & Son, Inc., in the Kantishna district. The total for 1941 considerably exceeded tonnages for 1938 to 1940 but was below the record for 1937. Much of the ore shipped from this deposit in 1941 was mined during 1939–40 and held in storage awaiting a more favorable market. Early shipments consisted of hand-sorted ore, but beginning in 1939 shipments comprised both ore and concentrates from a small mill installed in that year. In the early months of 1942 it was reported that the property had been acquired from Kirk by Earl Pilgrim, manager for Kirk since operations at the property were begun in 1936. It was also reported at that time that new milling equipment was to be installed.

Antimony deposits of the Stampede Creek area have been described in a report by Donald E. White of the Geological Survey, available for consultation in the Washington office of the Survey. White says that a large fault, the Stampede fault, has probably controlled the deposition of the antimony ore. The Stampede mine contains several veins or series of veins, one of which branches from the Stampede fault at a small angle. The veins are commonly wider and higher in grade near the premineral cross faults, which are tight and slightly mineralized. Several ore bodies have been found in the veins immediately east and north of cross faults—that is, on their hanging-wall sides. However, the largest ore body, called the Surface ore body, lay between the Stampede fault and the offshooting vein. The antimony is present principally as stibnite. White estimated that the reserves, including ore partly developed, amount to about 70 tons of shipping-grade ore containing at least 50 percent antimony and 6,000 tons of low-grade ore, capable of concentration, which has a minimum content of 10 percent antimony. In addition, the surface material below the outcrop of the principal ore body is estimated to contain at least 1,000 tons of oxidized ore with a tenor of 20 percent. Mill tailings amounting to 5,000 tons contain 6 percent antimony and may eventually be reworked. The estimates of reserves do not include possible ore in bodies not yet discovered or completely undeveloped ore in known bodies.

Mining at the Stampede mine was recently described.[2]

Arizona.—Less than 1 ton of antimony ore was produced and shipped from the Walker district in 1941. The mine in the Tip Top district, from which a small shipment was made in 1940, was inoperative during 1941.

California.—The Hilltop and Bishop properties in Inyo County produced antimony ores in 1941, and small quantities came from two properties in Kern and one in San Bernardino County. The location

[2] Gallaher, Robt. A., Sub-Arctic Antimony Mining. Mining World, vol. 3, No. 7, July, 1941, pp. 21–23.

of one producer was unreported. Some ore was also shipped in less than ton lots.

Production and shipments for the State amounted to only 51 tons of ore containing about 15 tons of antimony, marking a decline from the 74 tons containing 29 tons of antimony in 1940. Shipments in 1941 moved almost entirely to the El Segundo plant of Harshaw Chemical Co., near Los Angeles. This company took over the plant operated by Menardi Metals Co. in 1940.

Antimony deposits in the Stayton district, which lies 13 miles northeast of Hollister and includes parts of San Benito, Santa Clara, and Merced Counties, were described in a report that is one of a series on strategic minerals investigations.[3] According to the report, the antimony reserves of the district cannot be closely estimated because high-grade pockets are distributed sporadically. The breccia veins, exclusive of rich pockets, average less than 1 percent antimony, and, although the total amount of antimony they contain is a few tens of thousands of tons, the average grade is much too low for mining to be profitable, even at the high average price of 22 cents a pound that prevailed during the First World War years 1915–18. Small, high-grade pockets were not expected to raise the average tenor of any considerable length of breccia vein to more than 1½ percent.

Idaho.—As has usually been the case in the recent past, Idaho was the principal producer in 1941 of antimony ores and concentrates. Output amounted to 1,823 tons containing 655 tons of antimony, and shipments totaled 1,249 tons containing 483 tons of antimony. In addition to such ores, an even larger amount of antimony came from ores classed as silver ores, copper ores, and others, not included in this report as mine output of antimony. The Yellow Pine mine, operated by the Bradley Mining Co., is the largest source of antimony in the United States. This mine is owned by the United Mercury Mines, which also owns and operates the second-largest producing antimony mine in Idaho in 1941—the Antimony Ridge. Operations at the Yellow Pine mine were described by Bradley,[4] who stated that 492,977 tons of ore assaying $5.93 a ton in gold was milled from 1932, when the Yellow Pine Co. began operations (it was succeeded in 1938 by the Bradley Mining Co.), until January 1, 1941. The average net, smelter return for gold, silver and antimony was $4.17 a ton. During this 9-year period, 68,364 ounces of gold, 213,569 ounces of silver, and 7,875,878 pounds of antimony were recovered from the concentrates.

The Bureau of Mines has developed an important reserve of low-grade antimony ore in the Yellow Pine mine, in connection with its strategic metal program. Drilling has revealed 2,315,000 tons of ore containing 43,900 tons of antimony. This ore must be considered mostly subcommercial at normal prices, although it is believed that about 300,000 tons may prove commercial if proper milling equipment is used.

One other mine in Valley County and two properties in Shoshone County produced small quantities of antimony ore or concentrates in 1941.

Idaho antimony ores were shipped to the Texas Mining & Smelting Co., Laredo, Tex.; Harshaw Chemical Co. (also Menardi Metals Co.,

[3] Bailey, Edgar H., and Myers, W. Bradley, Quicksilver and Antimony Deposits of the Stayton District, California. Geol. Survey Bull. 931-Q, 1942, pp. 405–434.

[4] Bradley, John D., Mining and Milling Methods and Costs at the Yellow Pine Mine, Stibnite, Idaho. Bureau of Mines Inf. Cir. 7194, 1942, 11 pp.

which preceded it), El Segundo, Calif.; United States Smelting, Refining & Mining Co., Midvale, Utah; and Bunker Hill & Sullivan Mining & Concentrating Co., Kellogg, Idaho.

Montana.—Small quantities of antimony ores were produced and shipped in 1941 from near Thompson Falls in the Burns district, Sanders County. Mines and claims reported to have been active were the Stibnite Hill, Eureka, Ellis, Coeur d'Alene, and Interstate. Production and shipments totaled 113 tons containing 43 tons of antimony.

Nevada.—A greater number of antimony properties were active in Nevada than in any other State during 1941. Operations were reported in every section of the State, and the producing counties are given as follows, in descending order of importance: Nye, Lander, Pershing, Humboldt, White Pine, and Washoe. There were 16 shippers of lots of more than 1 ton each. The average size of antimony operations was small, and the average grade of ore produced was low, as is indicated by the fact that totals for the State were 691 tons, containing 146 tons of antimony, produced and 669 tons, containing 138 tons of antimony, shipped. A number of shipments of less-than-ton lots were made. The Harshaw Chemical Co. (which succeeded Menardi Metals), El Segundo, Calif., was the destination of the larger number of shipments, and the Texas Mining & Smelting Co., Laredo, Tex., received the remainder.

Oregon.—The chapter of this series, review of 1940, pointed out that prospecting was done on antimony deposits in Baker and Jackson Counties in that year. This work resulted in production and shipments of ore from both counties in 1941. Shipments of more than ton lots were made from the Gray Eagle (Koehler) and one other property in Baker County and from the Jay Bird in Jackson County.

Washington.—Two properties in Okanogan County were reported to have produced and shipped antimony ore in 1941—the Antimony Queen in the Methow district and the Lucky Knock in another district.

SMELTER OUTPUT

In 1941 primary antimony for shipment to others was produced from foreign and domestic ores at three plants in the United States: Bunker Hill & Sullivan Mining & Concentrating Co., Kellogg, Idaho; Harshaw Chemical Co., Menardi Metals Division, El Segundo, Calif.; and Texas Mining & Smelting Co., Laredo, Tex. In addition, metallic antimony was produced by the American Smelting & Refining Co. at its Omaha (Nebr.) plant but was converted into other products such as antimonial lead and was not sold as metallic antimony.

The Sunshine Mining Co. began to construct an antimony plant at Big Creek, Idaho (near Kellogg), early in 1942, to be in operation by late summer of that year. The plant will be the fourth in the United States and is designed to recover the antimony content of silver-bearing tetrahedrite ore mined by the company. It is planned to treat custom antimony ore as well. The capacity is reported to be 200,000 pounds of metal a month.

Imports of antimony ore in 1941 amounted to 41,662 short tons containing 19,386 tons of antimony, compared with 37,966 tons in 1940 containing 15,733 tons of metal, an increase of 23 percent in terms of antimony content. The following table, which shows consumption and stocks of foreign antimony in the United States during

1940 and 1941, lists receipts of 40,434 tons of ore in 1941 and 34,530 tons in 1940 or 97 and 91 percent, respectively, of the total amount imported. The difference in each instance is attributable to the usual lag in reporting imports on one hand and receipts on the other, plus the fact that a certain percentage of total stocks is in transit and not statistically accounted for in the receipts. Receipts exceeded consumption in 1940, and stocks of antimony ore increased 33 percent (gross weight). The reverse was true in 1941, and stocks declined 56 percent. Although receipts increased 17 percent over 1940, consumption of 46,211 tons (containing 20,530 tons of antimony) in 1941 was 44 percent above the reported consumption of 31,982 tons (containing 13,421 tons of antimony) in 1940.

Consumption and stocks of foreign antimony ore in the United States during 1940 and 1941, in short tons

	Gross weight of antimony ore	
	1940	1941
Stocks at beginning of year	7,775	10,323
Received during year	34,530	40,434
Consumed during year	31,982	46,211
Stocks at end of year	10,323	4,546

Production of antimonial lead at primary lead refineries is shown in the accompanying table. The figures cover only part of the total antimonial lead production, as large quantities are produced at plants that operate exclusively on scrap, and some hard lead is made by mixing antimony and soft lead.

Antimonial lead produced at primary lead refineries, 1937–41, in short tons

Year	Production	Antimony content				
		From domestic ores	From foreign ores [1]	From scrap	Total	
					Quantity	Percent
1937	27,524	1,636	90	853	2,579	9.4
1938	24,123	1,871	209	729	2,809	11.6
1939	21,995	929	179	923	2,031	9.2
1940	29,762	1,915	162	867	2,944	9.9
1941	40,237	2,586	372	552	3,510	8.7

[1] Includes lead ores, antimony ores, and metallic antimony.

SECONDARY PRODUCTION

A large part of the total antimony available for consumption each year in the United States is recovered in the treatment of secondary nonferrous metals. The production of antimony from secondary metals in 1941 totaled 21,629 tons—an 89-percent increase from the 11,421 tons produced in 1940. Primary antimony available for consumption in the United States in 1941 totaled 29,994 tons. Total antimony available was thus 51,623 tons, including 58 percent primary and 42 percent secondary; the ratios in 1940 were 61 and 39 percent, respectively.

Most of the secondary antimony is recovered from old scrap returning from worn-out and obsolescent equipment. In 1941, old scrap yielded 21,572 tons of antimony and new scrap 57 tons. Lead-base alloys, chiefly antimonial lead, supplied 99 percent of the total secondary antimony recovered in 1941; most of the remainder came from tin-base scrap. Discarded storage batteries are the largest single source of secondary antimony. In 1941 plants treating secondary metals reported the consumption of 264,190 tons of battery lead plates containing 12,681 tons of recoverable antimony or 59 percent of the total secondary antimony produced. Babbitt of all types, including Mixed Common, No. 1, and Genuine, yielded 2,347 tons of antimony, and 4,089 tons came from type metals and drosses. The remainder of secondary antimony in 1941 came from hard lead (yielding 2,268 tons of antimony), cable lead (216 tons), and No. 1 pewter (28 tons).

Most of the plants treating scrap metals containing antimony also consume other antimony materials, such as antimony ore or metallic antimony. These materials are used to adjust or "sweeten" the antimony content of the products. Refined metallic antimony is rarely produced from scrap metals, as most of the output is in the form of lead-base and tin-base alloys. Much of the production is in the form of antimonial lead returned directly to the storage-battery trade. Antimony oxide, sodium antimonate, and other compounds are also produced from scrap metals. Additional information on secondary antimony is given in the chapter on Secondary Metals—Nonferrous.

DOMESTIC CONSUMPTION

Data on the consumption of primary antimony in the United States are not available owing to the lack of complete information on dealer and consumer stocks and on the quantity of domestic antimony recovered in alloys other than antimonial lead and in compounds. Comprehensive surveys of producers and consumers of antimony and antimony materials are currently being conducted by the Bureau of Mines and should give a nearly complete picture for 1942. However, an approximate idea of the trend of consumption can be obtained from the following table, which shows the annual supply available for consumption.

Primary antimony available for consumption in the United States, 1937–41, in short tons [1]

	1937	1938	1939	1940	1941
Domestic antimony recovered in antimonial lead	1,636	1,871	929	1,915	2,586
Imports for consumption (antimony content)					
Antimony ore	13,818	8,322	9,448	15,733	19,386
Needle or liquated [2]	540	63	160	79	447
Compounds [3]	909	336	138	4	2
Type metal, etc	410	355	121	191	202
Regulus	1,043	821	1,045	209	7,460
Total available	18,356	11,768	11,841	18,131	30,092
Exports under draw-back	224	211	232	176	98
Available for consumption [4]	18,132	11,557	11,609	17,955	29,994

[1] Excludes domestic antimony recovered as miscellaneous alloys, oxides, and other compounds.
[2] Content estimated at 70 percent.
[3] Content estimated at 80 percent.
[4] Figures are low owing to somewhat incomplete data concerning some items of domestic production.

Primary antimony available for consumption in 1941 increased 67 percent over the total for 1940. Imports of regulus and ore increased to a marked degree, and domestic production also advanced. According to the American Bureau of Metal Statistics, 131,000 tons of antimonial lead were used in manufacturing storage batteries during the year compared with 115,600 tons in 1940 and 106,500 tons in 1939. This battery metal contains 4 to 12 percent antimony, largely from scrap, although a substantial quantity of new metal is added to raise the alloy to the required ratio.

An important use of antimony is in white-base antifriction bearing metals. According to the Bureau of the Census, shipments of this material produced for sale and for plant consumption in 1941 totaled 33,146 tons compared with 26,701 tons in 1940. The manufacturers reporting data that give the above totals represent almost the entire industry.

The use of antimony in making chemicals continued to grow in 1941, as the production of oxide and other compounds increased 43 percent to 14,588 short tons containing approximately 11,590 tons of metal. Figures on the production of compounds in the 4 preceding years, with the estimated antimony content in parentheses, are as follows: 1940, 10,211 tons (8,223); 1939, 7,668 tons (6,188); 1938, 4,393 tons (3,539); 1937, 6,992 tons (5,667). Nearly all of this material was made from foreign ores. Oxide, the most important compound, is used extensively in paints, lacquer, synthetic enamel, porcelain enamel, and glass. The following companies reported production of oxide and other salts in 1941: American Smelting & Refining Co., 120 Broadway, New York, N. Y.; Harshaw Chemical Co., 1945 East 97th Street, Cleveland, Ohio; McGean Chemical Co., 1106 Republic Building, Cleveland, Ohio; Menardi Metals Co., Division of Harshaw Chemical Co., El Segundo, Calif.; Texas Mining & Smelting Co., Laredo, Tex.; and Rare Metal Products Co., Belleville, N. J.

Still another and expanding use for antimony, although comparatively small, is in the treatment of canvas and other textiles against rotting and fire. The importance of such a use for military purposes at present is obvious.

PRICES

The price of domestic brands of metallic antimony was quoted at 14.00 cents a pound in New York throughout 1941, the same as in 1940. A one-half cent advance posted in August 1941 was quickly withdrawn at the request of the Office of Price Administration, and no further advance was made until March 23, 1942, when the quotation was listed at 15.96 cents by permission of Office of Price Administration. An additional allowed rise on April 13 brought the price to 16.01 cents, where it remained at the end of July 1942. The quotation of 16.50 cents a pound for Chinese metal, which had been in effect during all of 1940, remained the same throughout 1941 and was unchanged at the end of July 1942; the price was nominal.

On the London market the price of English regulus (minimum, 99 percent antimony) was £85 from December 31, 1940, until May 23, 1941, when it increased to £95. The quotation continued to advance during the following 5 months to £120 on October 10, where the price remained for the rest of 1941; it was still quoted at this level at the end of June 1942. Foreign regulus (spot deliveries from warehouse,

duty paid) was quoted at £90 at the end of 1940. Subsequent prices throughout 1941 and the first half of 1942 were the same as those of the English regulus.

Average monthly quoted prices of antimony, prompt delivery at New York, 1937–41, in cents per pound

[2] Metal Statistics, 1942, p. 551.
[3] Nominal.
[4] No average, owing to lack of offerings during greater part of month

Quotations for antimony ore on January 2, 1941, according to Engineering and Mining Journal Metal and Mineral Markets, were as follows: "Per (short-ton) unit of antimony contained, at New York, 50 to 55 percent, \$1.25 @ \$1.35; 58 to 60 percent, \$1.40 @ \$1.50; 60–65 percent, \$1.50 @ \$1.60. London, 60 to 65 percent, 9s.3d. per long-ton unit." Increased competition for the available ore supply resulted in higher prices which, by January 1, 1942, reached \$2.00 @ \$2.15 for the lower-grade ore, \$2.15 @ \$2.25 for intermediate-grade, and \$2.25 @ \$2.35 for higher-grade at New York, and 14s.9d. for higher-grade in London. These prices fluctuated slightly throughout the first month of 1942 but rose in April to \$2.15 @ \$2.20, \$2.20 @ \$2.30, and \$2.30 @ \$2.40 for the lower, intermediate, and higher grades, respectively. The New York quotations were unchanged at the end of July, but the London price for the higher-grade was quoted at 12s.9d. in May.

FOREIGN TRADE

The following tables show imports and exports of antimony and antimony products.

Antimony imported for consumption in the United States, 1937–41

Year	Antimony ore			Needle or liquated antimony		Antimony metal		Antimony oxides and other compounds	
	Short tons	Antimony content: Short tons	Antimony content: Value	Short tons	Value	Short tons	Value	Short tons	Value
1937	42,453	13,818	\$1,775,011	772	\$101,963	1,043	\$228,485	1,136	\$249,152

	41,662	19,386	2,717,472	7,469	2,056,678

[1] Imports credited to Argentina originate largely in Bolivia.

Estimated antimony content in type metal, antimonial lead, and other alloys imported for consumption in the United States, 1937–41, in short tons [1]

Year	Type metal and antimonial lead	Other alloys [2]	Total	Year	Type metal and antimonial lead	Other alloys [2]	Total
1937	[3] 17	393	410	1940	191		191
1938	[3] 59	296	355	1941	202		202
1939	59	62	121				

[1] For details of gross weight and values, see imports shown in Lead chapter of this volume.
[2] Chiefly in special antimony-lead alloys containing high percentage of antimony. [3] Type metal only.

Foreign antimony (regulus or metal) exported from the United States, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	437	$86,991	1940	276	$75,440
1938	711	96,836	1941	70	19,690
1939	58	16,736			

As in other recent years, imports of antimony ore in 1941 came principally from Mexico and Bolivia. Imports from Bolivia increased 26 percent in 1941, and receipts from Mexico were the highest on record, except for 1937 when 34,736 short tons were imported. Imports for consumption of 7,469 tons of antimony metal in 1941, nearly all from China, were the highest recorded since 1930.

In addition to the exports of foreign metal reported in the last table above, 98 tons were exported in finished products under the draw-back provisions of the tariff law; draw-back exports amounted to 176 tons in 1940 and 232 tons in 1939. Stocks of antimony in bonded warehouses on December 31, 1941, totaled 416 tons compared

with 3,417 tons at the end of 1940. The drop is due largely to the release of Chinese metal stocks held by the Metals Reserve Co.

WORLD PRODUCTION

Statistics on world production, which were incomplete for 1939 and 1940, are even less complete for 1941 because of the war and its effect on the release of information from the nations involved. Data from countries that supplied 84 percent of the total recorded world output in 1938 indicated a 14-percent increase over that year in total world production during 1940. Similarly, statistics from countries that produced 57 percent of the world total in 1938 indicate a 55-percent increase over that year in total world production during 1941. Although Mexican output decreased, the loss was more than offset by gains in Bolivia. All other countries from which data were available showed increases over 1940.

REVIEW BY COUNTRIES

Argentina.—During 1940 the total production of antimony ore in Argentina was approximately 250 tons, including antimony oxides, sulfides, and ores associated with silver, iron, copper, and arsenic. A corresponding figure for 1941 is not available. The source of antimony is chiefly small mountain mines in the Provinces of Jujuy and La Rioja. The Pabellon mine, Jujuy, is the principal producer. A small tonnage of antimony is obtained annually as a byproduct of imported Bolivian lead ores.

Bolivia.—The main antimony-producing regions in Bolivia are near Tupiza, Llallagua, and Oruro. The stibnite ore bodies are generally spotty, and the ore is mined and concentrated by rudimentary hand methods, which yield low recovery with a tailings content ranging from 5 to 10 percent. More than 80 percent of the total exports of antimony is supplied by the Banco Minero de Bolivia from purchased production of small miners. Recent demand for antimony has resulted in a steady increase in output, which reached 24,923 metric tons of ore containing 14,870 tons of antimony in 1941.

Brazil.—Several occurrences of antimony have been reported in Brazil, and the deposits of Morro do Bule, near Ouro Preto, State of Minas Gerais, and also Cananea, State of São Paulo, are considered of value for commercial exploitation.

Canada.—The high prices for antimony prevailing in the latter part of 1941 renewed the interest in the Stuart antimony deposit at Ferguson Creek, Bridge River district, British Columbia. This property was discovered in 1925 but has not been developed. Late in 1941 a considerable quantity of ore from the Bridge River area was sacked and shipped to the United States for treatment.

China.—Production from China during 1940 was 5,493 metric tons, including antimony content of regulus, crude antimony, and oxide exported. No figures for 1941 are available. New antimony deposits are being explored, with the expectation of increasing output 1,000 to 2,500 tons annually.

Approximately 99 percent of the antimony mines lie in southwestern China, in territory still under Chinese control. Exports from all of China during 1940 were 326 metric tons of crude antimony and 5,248 tons of regulus.

Late in 1941 Japanese military interests were reported to be organizing an antimony refinery at Wuchang, Hupeh, in central China, capitalized at yuan 3 million, but no other details are available.

Cuba.—Antimony is found in the MacKinley area in the northwestern part of the Isle of Pines, and small amounts were shipped to the United States in 1941.

Honduras.—A trial shipment of antimony ore (25 long tons) from a property near La Union, Department of Olancho, was sent to the United States in the third quarter of 1941. The Yoro Mining Co. and the Honduras Mining Co. have been idle during 1941, principally because transportation costs between the deposits and the ports of shipment have been too high for profitable operation.

India.—Several sources of antimony ore have been found recently in India as the result of exploration, and a refining plant to treat these ores may be installed in the near future.

Japan.—It is reported that increased output of antimony is planned by the semigovernmental antimony mining company in Japan. This step has been taken as a result of the ban imposed by Bolivia on exports of antimony to Japan. Current antimony production covers less than a quarter of Japan's consumption, which has risen sharply in recent years.

Mexico.—The most recent available information on the antimony industry in Mexico appears in the November 20, 1941, issue of Mineral Trade Notes, published by the Bureau of Mines, from which the following notes have been abstracted.

Deposits of antimony are found in 14 States in Mexico. Output from many of the discoveries has been small, but potentialities of several undeveloped deposits are promising. Lack of even medium-sized formal mining operations in the Mexican antimony industry is noteworthy. In only a few instances, notably at San Juan Mixtepec, Oaxaca, and at Wadley, San Luis Potosi, are properties large enough to justify installation of mechanical equipment. The greater portion of antimony comes from small, scattered operations, mostly close to the surface with very little depth attained by the workings. Likewise most of these operations are carried on under the "buscon" and "gambusino" systems, in which the individual miner is almost entirely the sole judge of where, when, and how the work is to be performed.

Up to a short time ago almost the entire production of antimony in Mexico was controlled by Cia. Minera y Refinadora and by Cia. Minera de Oaxaca. However, within the past few months, several other organizations and individuals have entered actively into the field, largely from the ore-purchasing angle.

The Republican Mining Co. was the earliest formal organization in Mexico for the production of antimony. This company was the forerunner of the Texas Mining & Smelting Co., of which Cia. Minera y Refinadora is a subsidiary. Cia. Minera de Oaxaca is owned mainly by the Madera Bros. of Mexico City, but the Texas company also has a substantial stock interest in it. Operations of Cia. Refinadora are confined generally to the area north of Queretaro, while Oaxacá operates to the south.

The principal antimony area is in the western part of Oaxaca near San Juan Mixtepec just west of Tlaxiaco. Cia. Minera de Oaxaca controls the most important developments in the area. During 1940 production in Oaxaca totaled 5,100 tons, averaging 56 percent antimony—2,900 tons of oxide ore and 2,200 tons of sulfide ore. The sulfide ore normally averages 52 to 57 percent Sb, while the oxides occasionally run as high as 80 percent.

The antimony deposits in the vicinity of Wadley, 165 kilometers north of San Luis Potosi, formed the nucleus for the mining operations of the Republican Mining Co. This company, originally organized by the Cookson interests of England, built a smelter at Wadley, which operated until 1930 when the Cookson interests were reorganized, the smelter closed, and a new plant opened at Laredo, Tex. The initial operation of the Republican Mining Co. was the San Jose mine, high in the hills about 7 miles east of Wadley. Originally, work on the property

was performed on company account, but, with the type of ore body found, this system proved unprofitable and upon reorganization of the corporation was abandoned. At present, work is conducted on the "gambusino" system, which in general principles corresponds to leasing operations in the United States. Development work in search of new ore bodies is done by the company, as the gambusinos are unwilling to perform work where there is no certainty of a direct return.

Just north of Wadley is the old mining district of Catorce with a considerable record of past production of precious metals, but now almost dormant except for a small output of antimony. This ore comes from small scattered operations, and the greater part is purchased by Refinadora and shipped to Laredo. Production from the district averages about 60 tons monthly, virtually 95 percent of which is oxide ore containing 25 percent Sb. Individual lots average from 20 to 40 percent. Between Catorce and Wadley, at Nantanzas, 60 to 80 buscones are producing about 80 tons of ore monthly.

The principal antimony-producing regions of the State of Queretaro lie in the central and eastern parts of the State in the vicinity of Toliman, Bernal, El Doctor, and Jalpan. The largest amount of development and greatest production has been in the area nearest Toliman and Bernal. In this section several other large mining operations have produced over a period of several years. At present the most active of these properties is owned and operated by Augustine B. Carrasco. Carrasco operates one of the few concentrating plants for the beneficiation of antimony ore. The plant uses gravity methods and is turning out 60 tons of 50-percent concentrate monthly. The mine also produces between 60 and 70 tons monthly of direct shipping ore.

The State of Zacatecas is one of the oldest mining areas in Mexico with a recorded production dating back to 1540 when the mines were first discovered by the Spaniards. In 1940 the State ranked sixth in output of antimony, when 201 tons were recovered. The chief antimony areas are in the northern part of the State in the vicinity of Sombrerete, Nieves, and Pacheco. Refinadora, which maintains agencies in the larger towns and even in small villages, has been the chief outlet for the ore. The deposits worked so far are small, irregular pockets close to the surface and with little indication of continuity. Operations have been carried on for several years, but no appreciable depth has been attained, rarely more than 15 to 20 meters.

During 1940 Durango produced only 161 tons of antimony, all reported by Refinadora as obtained from the Cuencame and San Bartolo districts. Scattered antimony deposits are reported in the State, but most of them are in the eastern and northeastern sections. The ore is comparatively low in grade, ranging from 25 to 30 percent.

Three widely separate districts in Sonora are known to contain deposits of antimony ore and to have shipped appreciable amounts in past years. These are near the village of Antimonio, about 100 miles west of Santa Ana on the Southern Pacific, 66 miles south of Nogales; Sahuaripa, in the central part of the State near the Chihuahua line; and in the vicinity of Nacozari, south of Douglas, Ariz. The Antimonio district, or as more generally called the Caborca district, has been an important source of antimony. Shipments have been made during the past 25 years and at the present average 100 tons of metal contained in ore monthly. The ore as shipped averages 45 percent Sb. The workings as yet have not reached any appreciable depth. It is reported that 25,000 tons of 10-percent ore have accumulated on dumps for possible future operations. The deposits in the neighborhood of Sahuaripa are virtually inaccessible. Small amounts of antimony are shipped occasionally, but up to the present the district has been of little importance. Occasional small shipments also are made from Nacozari. Small undeveloped deposits along the Yaqui River near Ramona have been reported.

Several antimony deposits are reported in the State of Guerrero, but to date only the Huitzuco Co. is operating. In June 1941 the company treated 110 to 130 tons of ore daily, averaging 0.23 percent Hg and 1.1 percent Sb. The ore is treated in a modern flotation plant, and the concentrates are shipped to Menardi Metals Co., Los Angeles, Calif., for refining. Production in 1940 totaled 335,155 pounds of antimony, of which 224,058 were recovered from refining operations.

Peru.—In 1941 exports of antimony ore from Peru totaled 2,850 metric tons containing 1,452 tons of metal, 48 tons of antimonial lead ores containing 11 tons of metal, and 2 tons of antimony bar containing 1.8 tons of metal. Antimony is largely mined by small pro-

ducers. It is reported that potentially large deposits occur in the Departments of Arequipa and Puno, but exploitation is restricted by lack of transportation facilities and capital.

The principal development in the antimony industry in Peru is the erection, by the Cerro de Pasco Corporation, of a dust treatment plant, of 100 tons a day capacity, which should be completed in 1942, pending arrival of equipment from the United States. The plant will treat Cottrell dust; 4,000 tons containing 45 percent antimony are stored at the smelter.

Union of South Africa.—According to the Metal Bulletin (London), the Consolidated Murchison (Transvaal) Goldfields and Development Co., Ltd., is now producing antimony flotation concentrates on a fairly substantial scale; these are, for the most part, being shipped to the United Kingdom for treatment. Several small mines are being worked along the Murchison range for the production of antimony alone.

CADMIUM

By Allan F. Matthews

SUMMARY OUTLINE

GENERAL STATEMENT

Cadmium recovery is at a high level in apparently all zinc-lead-smelting countries. More than half of the world output is supplied by the United States, a sixth by the British Commonwealth of Nations and the U. S. S. R., and about a fifth by the Axis-dominated countries. The favorable position of the United Nations is due in part to their control of the flow of cadmium flue dust from Mexico and South-West Africa. Cadmium production in the United States from domestic and imported raw materials reached about 7½ million pounds in 1941, and stocks were drawn upon to meet a consumption of nearly 8 million pounds. Germany was able to supplement its own cadmium output—the second-largest in the world—with quantities from Poland, Norway, and France. Canadian cadmium production, which ranks third, was increased about 30 percent in 1941.

Government supervision.—The job of maintaining production of cadmium in the United States and directing available supplies into war channels was undertaken by the Cadmium Section, Office of Production Management; in April 1941 Harry J. Wolf was appointed chief of the section. During the latter half of 1941 producers marketed their cadmium in normal fashion, although the Office of Production Management watched deliveries and stepped in to handle individually the "hot-spot" situations that developed. Cadmium was placed under full priority control by Office of Production Management Order M–65 on January 17, 1942. The companion Order M–65–a, issued at the same time, prohibited the use of cadmium in automotive, trailer, and tractor equipment, building supplies and hardware, house furnishings and equipment, and a number of miscellaneous products. Order M–65 was modified by an amendment, effective June 24, 1942, that enabled the War Production Board to allocate all cadmium for absolutely essential purposes. The Government stock pile of metallic cadmium, held by Metals Reserve Co., a subsidiary of the Reconstruction Finance Corporation, amounted to 134,400 pounds valued at $139,000 as of October 22, 1941, and was valued at $194,000 as of March 7, 1942. Control of cadmium imports was provided for in Office of Production Management Order M–63 on December 28, 1941, but was revoked by amendment 3, effective March 14, 1942,

because such imports were controlled by other means. During the last three quarters of 1941 primary producers cooperated with the Government in keeping the price of cadmium sticks at 90 cents a pound—the level at which it was formally fixed by Office of Price Administration Price Schedule 71, effective January 19, 1942.

DOMESTIC PRODUCTION

Cadmium established a new record in 1941, when primary production increased 14 percent over 1940. Production of secondary cadmium (derived principally from bearing scrap) now constitutes about 5 percent of the total primary and secondary output. Producers' shipments of primary cadmium were 10 percent larger in 1941 than in 1940. The geographic distribution of primary cadmium production, based upon location of plants that produced metal or compounds (and not upon origin of cadmium-containing ores), in 1941 was as follows: 74 percent from four plants in four Western States (Colorado, Idaho, Montana, and Utah), 18 percent from nine plants in six Central States (Illinois, Kansas, Missouri, Ohio, Oklahoma, and Texas), and 8 percent from six plants in three Eastern States (Connecticut, New York, and Pennsylvania). In the United States cadmium is chiefly a byproduct of zinc production.

Cadmium produced, shipped by producers, imported, and exported in the United States, 1937–41, in pounds

	1937	1938	1939	1940	1941
Production:					
Primary: [1]					
Metallic cadmium	4,265,973	4,077,961	4,411,530	[2] 6,154,200	6,937,931
Cadmium compounds (Cd content) [3]	[2] 418,800	[2] 216,400	[2] [4] 379,000	[2] 209,400	295,600
Total primary production	[2] 4,684,800	[2] 4,294,400	[2] [4] 4,790,500	[2] 6,363,600	7,233,500
Secondary (metal and Cd content of compounds) [5]	([6])	([6])	([4] [6])	227,900	379,500
Shipments [7] by producers:					
Primary:					
Metallic cadmium	4,059,764	2,525,666	5,190,273	6,467,260	7,044,417
Cadmium compounds (Cd content) [3]	334,600	211,000	[4] 401,200	205,900	265,700
Total primary shipments	4,394,400	2,736,700	[4] 5,591,500	6,673,200	7,310,100
Secondary (metal and Cd content of compounds) [5]	([6])	([6])	([4] [6])	227,200	376,500
Imports (metallic cadmium)	828,535	22,582	309,874	27,491	[8] 147,378
Exports (metal and Cd content of compounds)	([6])	([6] [9])	([6])	387,100	[8] 103,500

[1] Figures showing primary cadmium production for 1940 and 1941 are strictly comparable. The revised data for 1937–39 are exactly comparable with 1940–41 as to totals, but in the former period the cadmium content of some compounds made from metal is included with the compounds and excluded from the metal. Production figures prior to 1937 are comparable with 1937–39 data regarding metal output but are not comparable with 1937 or later data as to compounds or totals because the earlier figures include some duplication of metal made into compounds.
[2] Revised figures.
[3] Excludes compounds made from metal.
[4] Some secondary compounds included with primary compounds. Bureau of Mines not at liberty to publish figures separately for primary cadmium compounds.
[5] Bureau of Mines not at liberty to publish figures separately for secondary cadmium compounds.
[6] Data not available.
[7] Figures for 1937–39 represent sales.
[8] Figures cover January to September, inclusive.
[9] Producers reported exports of 458,283 pounds of metallic cadmium.

Cadmium compounds are produced principally from metal, although some are made directly from primary residues and secondary materials. Total production of cadmium compounds in 1941 (in terms of Cd content) increased 56 percent over 1940.

Cadmium compounds produced in the United States, 1940–41, in pounds

Compound	1940		1941	
	Gross weight	Cd content	Gross weight	Cd content
Cadmium sulfide [1]	2,287,608	759,500	3,304,478	1,141,500
Cadmium oxide [2]	318,393	260,800	410,748	361,300
Cadmium nitrate	29,594	10,800	138,951	50,600
Cadmium hydrate	[3] 19,799	[3] 14,100	42,095	31,500
Cadmium chloride	15,475	7,600	57,828	30,100
Cadmium carbonate	14,733	9,600	36,806	24,100
Cadmium bromide	6,289	2,500	17,041	7,000
Cadmium sulfate	4,324	2,200	6,771	3,400
Cadmium iodide	(3)	(3)	4,047	1,300
Cadmium acetate	1,103	500	1,300	600
Total production	2,697,318	1,057,600	4,020,965	1,651,400

[1] Includes cadmium lithopone and cadmium sulfoselenide.
[2] In addition to quantities shown, cadmium oxide consumed in making other compounds shown was produced as follows: 1940, 33,186 pounds (Cd content, 28,700 pounds); 1941, 33,649 pounds (Cd content, 27,500 pounds).
[3] Cadmium iodide included with cadmium hydrate to avoid disclosure of confidential figures.

CONSUMPTION AND USES

Consumption of cadmium in all forms in 1941 totaled 7,766,000 pounds, a 26-percent increase over 1940. Corresponding data for earlier years are not available. About 95 percent of the available cadmium is consumed in electroplating, bearing alloys, and pigments, and the remaining 5 percent goes into miscellaneous alloys, laboratory reagents, and photographic chemicals.

Electroplating.—The most common use of cadmium is as a protective coating for steel and, to a much lesser extent, for copper alloys. The principal advantages of cadmium electrodeposits as compared with

Estimated distribution, by uses, of cadmium consumed in the United States, 1940–41

Use	1940		1941	
	Pounds	Percent of total	Pounds	Percent of total
Electroplating	3,692,000	59.8	4,586,000	59.1

those of zinc, according to Fusco and Woldman,[1] Mankowich,[2] and Bray,[3] are as follows: (1) Coatings one-third as thick give equal protection; (2) rate of deposition is virtually double; (3) parts are more easily soldered; (4) cadmium has higher electrical conductivity; (5) when plated on one of two dissimilar alloys—such as steel and duralumin or steel and brass—that would otherwise be in contact, cadmium more effectively minimizes corrosion by galvanic action; (6) bath is more easily operated; (7) less electrical current is required; (8) cadmium has superior throwing power, that is, ability to deposit uniformly in recesses; (9) cadmium has greater resistance to atmospheric agencies, salt water, and alkalies; and (10) cadmium holds its brightness longer. Some of these properties are interrelated. A disadvantage of cadmium plating is its low resistance to many acids.

Products commonly electroplated with cadmium include bolts, nuts, screws, rivets, nails, washers, fasteners, and parts for a wide variety of products, including airplanes, ordnance, automobiles, electrical equipment (conduit fittings, switches, and controls), builders' hardware (locks, hinges, and fixtures), communication equipment (radio, telephone, and telegraph parts), office equipment (typewriter, adding-machine, and calculator parts), household appliances (vacuum-cleaner, washing-machine, stove, and refrigerator parts), hand tools (wrenches, pliers, and screw drivers), industrial hardware (chains, hose couplings, valves, hooks, filters, and pulleys), textile machinery (heddles, bobbin rings, and cotton-gin ribs), measurement and control equipment (counter, thermostat, pyrometer, and gage parts), machine tools, railway signal devices, agricultural implements, oil-drum flanges, commercial refrigerators, beverage and candy vending machines, respirators, fire-fighting apparatus, bicycles, buttons on work clothes and uniforms, fishing tackle, and toys. Many of the nonessential applications of cadmium have been discontinued for the duration of the war.

Cadmium bearing alloys.—Cadmium-base bearings are generally of two types—one composed of 98.65 percent cadmium and 1.35 percent nickel and another containing 0.?–2.25 percent silver and 0.25–2 percent copper in place of the nickel. Such bearings are used principally in automotive engines but also in aircraft and marine engines. The big end bearing of British Bristol and French Gnome-Rhone airplane engines was reported by German metallurgists to be of the first type mentioned.[4] Certain lead-antimony-tin bearing alloys contain 0.5–2 percent cadmium. Cadmium-base bearings, according to Dayton and Faust,[5] are stronger than babbitt and, compared with other connecting-rod bearings, have superior embeddability and ease of bonding but inferior seizure resistance and corrosion resistance. To protect cadmium bearings from the corrosive action of organic acids in lubricants, a coating of indium is sometimes applied. "Graphalloy"—solid graphite impregnated with 30–35 percent cadmium—is used in oilless bearings and bushing linings.

Cadmium solders.—The most widely used cadmium solders are the cadmium-silver solders, three typical compositions of which are shown

[1] Fusco, Anthony J., and Woldman, Norman E., Cadmium Plating in the Victory Program: Iron Age, vol. 149, No 12, March 19, 1942, pp. 46–52.
[2] Mankowich, A., Corrosion Resistance of Cadmium and Zinc Electrodeposits under Marine Conditions: Monthly Rev. Am. Electroplaters' Soc., vol. 27, No. 11, November 1940, pp. 833–839

[4] Iron Age, Metallurgy of Aircraft Engines: Vol. 148, No. 26, December 25, 1941, p. 40.
[5] Dayton, R W., and Faust, C. L., The Use of Silver in Bearings; Silver in Industry: Reinhold Publishing Corporation, New York, 1940, p. 223.

in the following table. Silver solders for the jewelry trade sometimes contain 10–20 percent cadmium. The zinc-tin alloy shown is a high-temperature solder suitable, among other things, for flexible tubing. Similar alloys containing 5–43 percent cadmium are used for soldering aluminum. The war-imposed necessity for strict conservation of tin has focused attention on reduction or even elimination of tin in base-metal solders. The cadmium-lead-tin alloys in the table appear the most promising of the low-tin solders, according to Rhines and Anderson,[6] who discuss the technical advantages and disadvantages of a number of cadmium solders. These investigators point out that base-metal solders containing no tin are distinctly less promising than those containing reduced quantities, but that the first two tinless compositions in the following table deserve special notice. The third tinless solder listed is one of the best, states Gillett,[7] for it resembles lead-tin in ease of application and makes good joints. It is alleged to be the favorite German substitute solder.

Cadmium solder compositions, in percent

Type	Cadmium	Silver	Zinc	Lead	Tin	Copper	Nickel
Silver-cadmium	5	20	30			45	
	95	5					
	16	50	16			15	3
Zinc-tin-cadmium	22.5		71		5	1.5	
Lead-tin-cadmium	26			65	9		
	22			75	3		
Tinless-cadmium	10–26			65–80			
	40		60				
	8		2	90			

Other cadmium alloys.—The addition of about 1 percent cadmium to copper trolley wire improves strength and wear resistance without seriously reducing electrical conductivity. Small quantities of cadmium-copper have also been used in electrical contact parts of horn relays and voltage regulators for automobiles. An alloy of 60 percent cadmium and 40 percent zinc is sold for hot-dipping wire. Some wire is dipped in a bath of 33 percent cadmium and 67 percent zinc. Photoengravers use zinc alloys containing 0.3 percent cadmium to improve etching characteristics. "Cerrobend," a low-melting alloy of 50 percent bismuth, 27 percent lead, 13 percent tin, and 10 percent cadmium, is used in the aircraft industry as a filler in bending thin-walled tubing and as a material for making spotting fixtures and jigs. Other low-melting alloys containing 39–50 percent bismuth, 19–38 percent lead, 11–24 percent tin, and 4–25 percent cadmium are used in sprinkler apparatus, fire-detector systems and valve seats for high-pressure gas containers. About 0.4 percent cadmium is added to some type metals to improve castability. Cadmium-carbon and cadmium-silver are made into contacts for circuit breakers and other electrical equipment. Small quantities of cadmium are used in slider fasteners, collapsible tubes, standard cells, pattern metal for stoves, low-carat gold alloys, and wire-quenching mediums, and as a deoxidizing agent in silver melting.

Cadmium compounds.—Cadmium sulfide and cadmium sulfoselenide are standard agents for producing resistant yellow and red colors,

respectively, in paints, ceramics, inks, rubber, leather, and other products. Virtually all the cadmium oxide, hydrate, and chloride produced go into platers' electrolytic solutions. Cadmium bromide, chloride, and iodide are used in photographic films.

STOCKS

Producers' stocks of cadmium during 1941 decreased 12 percent—the result of a 19-percent decline in metallic cadmium and a 50-percent gain in cadmium compounds (based upon Cd content). Inventories held by cadmium-compound manufacturers (consumers of metal in making compounds for sale) and suppliers (dealers plus distributors that cast metal into anode shapes) decreased 53 percent and 32 percent, respectively, during 1941. Consumers' stocks of cadmium in the first half of 1941 declined 11 percent but showed a net gain of 5 percent for the year. Metals Reserve Co., a subsidiary of the Reconstruction Finance Corporation, began a Government stock pile of metallic cadmium in 1941 and had on hand 134,400 pounds as of October 22 of the year.

[1] Partly estimated. Includes some material in process. Excludes stocks of compounds held by pigment and chemical consumers.
[2] Stocks on Oct. 22, 1941. Data for Dec. 31, 1941, are not available for publication.

PRICES

The 1941 opening price of 80 cents a pound for commercial sticks of metallic cadmium advanced 5 cents on February 17 and again on March 7 to 90 cents a pound, where it remained the rest of the year. Anode shapes continued to command a premium of 5 cents a pound. The tight position in plating metals enabled certain dealers to sell cadmium at prices as high as $1.75 a pound—a practice that on April 11 brought a charge of "ruthless profiteering" and a warning of ceiling prices from Leon Henderson, Commissioner of Price Stabilization, Office of Emergency Management. On August 30 Henderson, now Administrator, Office of Price Administration, announced that the major producers of cadmium had indicated their willingness to continue to sell the metal to consumers at prices not above 90 cents for sticks and 95 cents for anodes and to sell to distributors at discounts permitting resales at the same prices. This agreement, which was adhered to by primary producers but not by certain secondary producers, was made mandatory by Office of Price Administration Price Schedule 71, effective January 19, 1942. The order was

amended, effective June 22, 1942, to permit the sale of metallic cadmium in small containers (5 pounds or less) at October 1941 price levels.

Shipments of metallic cadmium, as reported to the Bureau of Mines by primary producers, had an average value of 78 cents a pound in 1941 compared with 70 cents in 1940, 53 cents in 1939, 74 cents in 1938, and $1.12 in 1937. Producers' quotations, according to Metal and Mineral Markets, averaged 88 cents in 1941 compared with 80 cents in 1940 and 59 cents in 1939.

Cadmium compounds also advanced in price during 1941—cadmium sulfide from 75 cents a pound to $1.10 in April and cadmium lithopone from 50–60 cents a pound to 55–65 cents in November, according to Oil, Paint and Drug Reporter.

FOREIGN TRADE [8]

Imports.—Imports of metallic cadmium in 1937–41 are shown in the following table. Virtually all of the metal entered from Canada in the first 9 months of 1941 was purchased by a French company and, as a result of the collapse of France, was resold to the Metals Reserve Co. A few hundred pounds of cadmium sulfide from the United Kingdom represented the total cadmium-compound entries reported in the first 9 months of 1941. Corresponding data on cadmium-compound imports in previous years are not available. Domestic cadmium production is partly from imported flue dust, which in the first 9 months of 1941 had a cadmium content of 1,707,022 pounds, including 1,370,294 from Mexico, 334,137 from South-West Africa, and 2,591 from the Union of South Africa. All flue dust imported in 1940 was from Mexico and contained 1,890,528 pounds of cadmium.

Metallic cadmium imported for consumption in the United States, 1937–41

Exports.—Cadmium exports in the first 9 months of 1941 totaled 103,500 pounds, including 46,516 pounds of metal and 57,000 pounds in compounds. Exports in 1940 comprised 286,529 pounds of metal and 100,600 pounds in compounds—a total of 387,100 pounds. These figures were obtained by the Bureau of Mines from exporters, and corresponding data for previous years are not available. The Department of Commerce, which had previously recorded data on

[8] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

cadmium exports in combination with other commodities, began to show them separately on July 1, 1941.

TOXICOLOGY

Dangers to health are involved in the production of cadmium and in the consumption of food contaminated with cadmium. Regarding the former, Frant and Kleeman [9] state: "Cadmium presents its greatest hazard to the health of man during its production and in the handling of its compounds. Most dangerous are the inhalation of fumes and vapors arising from retorts or condensers while cadmium and cadmium oxide are being manufactured and the inhalation of dust in bagging and handling the materials." In a number of instances inhalation of cadmium fumes has resulted in death. The safe limit of cadmium vapor in air is stated to be 0.1 milligram per cubic meter. The determination of cadmium in quantities as small as 0.025 to 0.05 milligram by a method suitable for industrial-hygiene studies is described by Feicht, Schrenk, and Brown [10], of the Bureau of Mines.

Several outbreaks of cadmium food poisoning induced the Federal Security Agency to advise manufacturers against using the metal for plating cooking utensils and refrigerator containers, according to an announcement by Federal Security Administrator Paul V. McNutt on January 14, 1942. The suggestion was implemented by action of the Office of Production Management, which stated that no cadmium would in future be released for such uses. New York City amended its Sanitary Code to prohibit the use of cadmium in articles employed in the preparation of food and drink. Most of the reported cases [11] of cadmium poisoning resulted from placing gelatin desserts and beverages containing fruit juices in cadmium-plated refrigerator trays. Cadmium was applied to the trays not by manufacturers but by reconditioners who sold the refrigerators second-hand. Cadmium-plated pitchers, beverage cans, roasting pans, and molds for "popsicles" (flavored ices frozen on a stick) also have caused food poisoning. Cadmium compounds combine with hydrochloric acid in the gastric juices to form toxic cadmium chloride, resulting in violent acute gastritis with nausea, cramps, vomiting, diarrhea, and weakness. Symptoms may appear within 10 minutes after ingestion of the contaminated food. Cadmium in concentrations as low as 15 parts per million produces noticeable effects. However, no fatal cases of cadmium food poisoning and no instances of chronic poisoning due to continued ingestion of minute amounts of cadmium have ever been reported.

WORLD ASPECTS OF CADMIUM INDUSTRY

Some general comments on the world cadmium situation appear in the opening paragraph of this chapter. Cadmium production of individual countries in recent years is shown in the following table.

[5] Revised figures.

Belgium.—Produits Chimiques de Tenderloo S. A., whose plant was reported seriously damaged by an explosion early in 1942, was a producer of cadmium and cadmium salts.[12]

Canada.—Production of cadmium in 1941 was stepped up 37 percent over 1940 by Consolidated Mining & Smelting Co. of Canada, Ltd., Trail, British Columbia—the Dominion's principal source of this metal. Hudson Bay Mining & Smelting Co., Flin Flon, Manitoba—the other Canadian cadmium producer—increased its milling capacity about 14 percent during 1941 and in September put into operation a 10-ton pilot plant to test a process for treating stock-piled residues containing zinc, cadmium, and other metals.[13] Canada is not only producing enough cadmium for its own requirements, according to a statement by the Metals Controller's Office,[14] but has a surplus to send to the United Kingdom and the United States. Primary cadmium may be acquired only under permit from the Metals Controller, according to an order effective June 1, 1942. Metallic cadmium, ton lots, was quoted at $1.15 a pound at the beginning of 1941, according to Canadian Metals & Metallurgical Industries, but advanced in March to $1.25 and in April to $1.30, where it remained the rest of the year.

Mexico.—Cadmium flue-dust production (based upon Cd content) was 11 percent larger in 1941 than in 1940. Cadmium flue dust was exported to the United States for production of metal and compounds.

Peru.—A cadmium recovery plant was under construction early in 1942 at the Cerro de Pasco Copper Corporation smelter in Oroya.[15]

[14] Northern Miner, vol. 27, No. 47, February 12, 1942, p. 7.
[15] Huttl, John B., A Mining Tour of South America: Eng. and Min. Jour., vol. 143, No. 6, June 1942, p. 49.

South-West Africa.—Cadmium flue dust is a byproduct of the smelting of copper-lead-zinc ores from the Tsumeb mine. The property was not worked during 1941, but in the first half of the year all remaining stocks of cadmium flue dust (containing 36 percent Cd) were shipped to the United States.

Sweden.—All local stocks of cadmium bars, rods, and anodes were requisitioned by the Swedish Government on November 1, 1941.

United Kingdom.—The purchase of cadmium metal, residues, and scrap (containing over 50 percent Cd) in the United Kingdom except by license of the Minister of Supply is prohibited by Control of Nonferrous Metals Order 6 (Cadmium), issued December 24, 1941, and effective January 1, 1942. Consumers of 10 pounds or less a month are exempt from the license requirement. The order also established a maximum price for cadmium ingots, sticks, and rods (99.9 percent Cd) at 5 s. 4 d. a pound in hundredweight lots and 5 s. 6 d. in smaller quantities.

PLATINUM AND ALLIED METALS

By H. W. Davis

SUMMARY OUTLINE

SUMMARY

Chiefly as a result of refining concentrates from Canada and crude platinum from Alaska, most of which heretofore has been done in England, recoveries of new platinum metals by refiners in the United States amounted to 152,623 ounces in 1941—a new record. Recoveries of new platinum metals gained 222 percent over 1940 and 80 percent over the former peak attained in 1926. Refinery capacity has been increased to handle larger quantities of Canadian concentrates. Production of domestic placer platinum metals was 26,821 ounces in 1941, a 21-percent decline from 1940. Sales of platinum metals to consumers in the United States advanced to 288,397 ounces in 1941 from 206,890 ounces in 1940. A greater quantity of platinum metals was used in industrial products and equipment than in jewelry in 1941. Imports of platinum metals established a new peak in 1941 and amounted to 309,995 ounces, an increase of 58 percent over 1940 and 1 percent over the previous record made in 1939. On the other hand exports of unmanufactured platinum metals were only 15,405 ounces in 1941, or 72 percent less than in 1940.

Despite the greatly increased demand for platinum metals in 1941, prices remained virtually unchanged throughout the year for all metals except iridium, which was reduced $100 an ounce in February.

[1] Subject to revision.
[2] In 1941 includes 17,027 ounces (8,427 in 1940) of new platinum from domestic sources, comprising 15,219 ounces (3,957 in 1940) derived from crude placer platinum, 3 ounces (none in 1940) from ore, and 1,805 ounces (4,470 in 1940) obtained from domestic gold and copper ores as a byproduct of refining.
[3] In 1940 figures exclude stocks held in United States by dealers and importers other than from the United Kingdom.
[4] Not separately classified.

Because of the demand for iridium for use in contact points for magnetos, voltage regulators, and other electrical applications in the war program, the Office of Production Management on July 3, 1941, requested the voluntary cooperation of refiners and others in discontinuing the use of iridium in platinum alloys for jewelry articles and in substituting 5 percent ruthenium-platinum alloys. Effective December 12, 1941, however, the use of iridium and its alloys in the manufacture of jewelry was prohibited under Conservation Order M-49.

Because of an insufficient supply of rhodium for war and essential civilian requirements, its use in the manufacture of jewelry was prohibited by the War Production Board under Conservation Order M-95, effective March 11, 1942. This order was amended April 1, 1942, to prohibit the use of rhodium alloys, as well as rhodium plating, in the manufacture of jewelry and other articles of personal adornment.

To prevent any American platinum from being smuggled out of the country or otherwise finding its way into enemy hands, all traffic in platinum except that conducted through normal, approved trade channels was halted by the War Production Board under general Conservation Order M-162, effective May 30, 1942.

CRUDE PLATINUM

Production.—Mine returns for 1941 indicate a production of 25,400 ounces of crude platinum (containing 22,630 ounces of platinum-group metals valued at $813,000) in Alaska,[1] 1,300 ounces in California, 41 ounces in Montana, and 80 ounces in Oregon—a total of 26,821 ounces; comparable figures for 1940 are 32,300 ounces of crude platinum (containing 28,886 ounces of platinum-group metals valued at $1,093,000) in Alaska, 1,400 ounces in California, 31 ounces in Montana, and 69 ounces in Oregon—a total of 33,800 ounces. Production in Alaska came mainly from placer deposits in the Goodnews district of southwestern Alaska; most of it was mined by a large modern dredge and by well-mechanized draglines. In California most of the output of platinum was a byproduct of dredges working the gold placers in Amador, Butte, Merced, Placer, Sacramento, San Joaquin, Shasta, Stanislaus, Trinity, and Yuba Counties. Production in Montana was from Lewis and Clark and Sanders Counties. Production in Oregon came from Baker, Grant, Jackson, and Josephine Counties.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1941, 6,494 ounces of platinum metals were recovered as a byproduct of refining gold and copper ores compared with 7,774 ounces in 1940

The Goodnews (Alaska) platinum deposits have been described by Mertie.[2] The report covers the geography, general geology, and economic geology of the platinum deposits and is illustrated with topographic and geologic maps. It includes 28 commercial analyses of platinum metals of Fox Gulch and Platinum Creek, 8 of Squirrel Creek, 47 of Lower Platinum Creek and Salmon River, and 1 of Clara Creek.

Purchases.—Platinum refiners in the United States reported purchases of domestic crude platinum from the following sources in 1941: Alaska, 25,752 ounces; California, 1,129 ounces; Montana, 10 ounces;

[1] Figures and other information for Alaska from Geol. Survey, U. S. Dept. of Interior.
[2] Mertie, J. B., Jr., The Goodnews Platinum Deposits, Alaska: Geol. Survey Bull. 918, 1940, 97 pp.

and Oregon, 126 ounces—a total of 27,017 ounces (6,006 ounces in 1940). Domestic refiners also reported purchases of 38,124 ounces (34,374 ounces in 1940) of foreign crude platinum or osmiridium in 1941—10 ounces from Canada, 37,790 ounces from Colombia, 224 ounces from Australia, and 100 ounces from the Union of South Africa.

Prices.—Buyers reported purchases at $28.39 to $73.28 an ounce for domestic crude platinum and $24.80 to $191.50 an ounce for foreign crude platinum or osmiridium in 1941.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, nickel, and copper indicate that 152,623 ounces of platinum metals were recovered in the United States from such sources in 1941, an increase of 222 percent over 1940 and 80 percent over the previous record made in 1926. It is estimated that 22,683 ounces of the total output in 1941 were derived from domestic sources.

New platinum metals recovered by refiners in the United States in 1941, by sources, in troy ounces

	Platinum	Palladium	Iridium	Osmium	Rhodium	Ruthenium	Total
Domestic from—							
Crude platinum	15,219	9	637	206	24	79	16,174
Ore	3	10	2				15
Gold and copper refining	1,805	4,645	33	11			6,494
	17,027	4,664	672	217	24	79	22,683
Foreign from—							
Crude platinum Nickel and copper refining	81,349	45,148	720	47	1,956	720	129,940
Total recovery	98,376	49,812	1,392	264	1,980	799	152,623

New platinum metals recovered by refiners in the United States, 1937–41, in troy ounces

Year	Platinum	Palladium	Iridium	Others	Total
1937	36,174	5,945	1,998	1,141	45,258
1938	30,444	3,653	1,247	869	36,213
1939	36,033	3,491	1,051	866	41,441
1940	38,951	4,564	1,517	2,307	47,339
1941	98,376	49,812	1,392	3,043	152,623

Secondary metals recovered.—In 1941, 51,569 ounces of secondary platinum metals were recovered from the treatment of scrap metal, sweeps, and other waste products of manufacture that contain platinum, a 22-percent decrease from 1940.

Secondary platinum metals recovered in the United States, 1937–41, in troy ounces

Year	Platinum	Palladium	Iridium	Others	Total
1937	55,926	12,680	2,076	1,524	72,206
1938	44,654	13,489	1,253	4,895	64,291
1939	45,432	13,039	2,767	2,205	63,443
1940	47,657	14,773	1,365	2,635	66,430
1941	37,522	12,630	659	758	51,569

Prices.—Except for iridium, quotations [3] on platinum metals were stable throughout 1941. Platinum was quoted at $36 an ounce, palladium $24, osmium $45 to $48, rhodium $125, and ruthenium $35 to $40. Iridium was quoted at $275 an ounce during January and at $175 the remainder of the year. The quotations on palladium, rhodium, and ruthenium have prevailed for several years.

Consumption and uses.—Platinum and its allied metals (palladium, iridium, rhodium, ruthenium, and osmium) are characterized by high melting point, whiteness, and resistance to oxidation at high temperatures and to attack by destructive chemical compounds. As pure metals, combined, clad, or alloyed with other metals, the platinum metals are employed in jewelry and dentistry, in the chemical and electrical industries, and for numerous miscellaneous purposes.

A material gain in world output of platinum metals, owing chiefly to improvements in metallurgical processes for refining copper-nickel ores, has made available large quantities of platinum, palladium, iridium, rhodium, ruthenium, and osmium. In 1938—the latest year for which fairly complete figures are available—world production of platinum metals was about 540,000 ounces, of which 57 percent was recovered as byproducts in the refining of nickel, copper, and gold ores, whereas in 1929 world production was about 231,000 ounces, of which 17 percent was so obtained. With increased supplies, relative stability in the price of platinum and palladium has been reached at levels that permit their use for plant equipment and other industrial purposes. Despite the rapid advance in output of platinum metals during the past decade, research has found new uses for them, and developmental activities are opening up larger and more diversified markets in which they are becoming accepted.

The most widely used metal of the group is platinum, which constituted 190,075 ounces (66 percent) of the total platinum metals reported sold to consumers in the United States in 1941. The chemical industry, which usually ranks second as a consumer of platinum, advanced to first place in 1941, taking 36 percent (68,285 ounces) of the total platinum sales. The largest outlet for platinum in the chemical industry in 1941 was as a catalyst to produce nitric and sulfuric acids, which are consumed in large quantities for the manufacture of explosives and other war materials. Important quantities of platinum were also used in laboratory ware and rayon spinnerets. Smaller amounts were employed in nozzles for the production of glass fiber, lining processing and reaction vessels, hydrogenation of organic compounds, glass insulators for the bases of electric-light bulbs, tubing, valves, siphons, and safety disks for handling corrosive liquids and gases, anodes for the production of "per" salts, gas-analysis cells, and crucibles.

The jewelry industry dropped from first to second place as a consumer of platinum in 1941. Alloyed with iridium or ruthenium, platinum is employed as a setting for diamonds and other precious stones in rings and other forms of jewelry. About 35 percent (66,151 ounces) of the total sales of platinum went to the jewelry trade in 1941.

Accounting for 15 percent (28,368 ounces) of the total platinum sales in 1941, the electrical industry ranked third. Platinum is used in this industry for thermocouples, temperature measuring and re-

[3] Engineering and Mining Journal Metal and Mineral Markets, vol. 12, 1941.

cording instruments, precision resistance thermometers, high-temperature furnace windings, spark-plug electrodes, magneto contacts, electrical contacts, relays, thermostats, automobile voltage regulators and direction indicators, and switches for potentiometric recorders.

The dental industry purchased 10 percent (19,426 ounces) of the total platinum sold in the United States in 1941. Platinum, either pure or alloyed, is used in tooth pins, bridges, and bracing for artificial teeth, as matrices on porcelain inlays, and in orthodontic appliances.

Next to platinum, palladium is the most extensively used metal of the group; it is about half as common as platinum but less costly. It constituted 78,904 ounces (27 percent) of the total platinum metals sold to domestic consumers in 1941. Palladium, pure or alloyed, is adapted to many of the uses of platinum and during the past 2 decades has been employed in increasing quantities by the dental, electrical, and jewelry industries. The conservation of gold by many countries has stimulated the demand for platinum metals, particularly palladium, and the substitution of palladium for gold alloys for dental restorations and articles of jewelry has made substantial progress. Palladium in telephone relays and other types of electrical contacts found an improved market in the electrical field; in consequence,the electrical industry was the chief consumer in 1941, taking 45 percent (35,456 ounces) of the total palladium sold. Second in magnitude as a consumer of palladium is the dental industry, which took 40 percent (31,440 ounces) of the total. The jewelry industry was the third-largest outlet for palladium in 1941, and small quantities were sold for use in the manufacture of chemical ware.

The consumption of the other platinum metals—iridium, rhodium, osmium, and ruthenium—is comparatively small; it made up 7 percent of the total for the group in 1941. Iridium is used chiefly as a hardening addition to platinum, rendering it suitable for laboratory vessels, rayon spinnerets, surgical tools, hypodermic needles, magneto and electrical contacts, and jewelry. Its compounds are employed as fixing agents, porcelain pigment, and (in the form of black) as a catalyst. Rhodium is alloyed with platinum for high-melting-point thermocouple wire, furnace windings, and laboratory ware for certain special applications, and for use as a catalyst to produce sulfuric acid and for ammonia oxidation to produce nitric acid and nitric oxide. Rhodium plating is employed as a finish for glassware and silverware and in surfacing reflectors for searchlights and projectors. Osmium, in association with other metals, provides pen points that will resist wear and corrosion by ink. Considerable osmium was used in electrical contact points in 1941. Osmium alloys also replace jewels as bearings for fine instruments. The oxide is used as a biological stain for fats and for fingerprint work. Ruthenium, like iridium, is an effective hardening agent for platinum and palladium, and one of its salts serves as a biological stain. Because of the demand for iridium in the aircraft industry, much ruthenium was employed as a hardener of platinum in jewelry and electrical contact points in 1941.

The following table shows sales of platinum metals by refiners, importers, and dealers to consumers in the United States in 1941. Such sales totaled 288,397 ounces.

Platinum metals sold to consuming industries in the United States in 1941, in troy ounces

Industry	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
Chemical	68,285	3,342		
Electrical	28,368	35,456		
Dental	19,426	31,440	19,418	288,397
Jewelry	66,151	7,999		
Miscellaneous and undistributed	7,845	667		
	190,075	78,904	19,418	288,397

Stocks.—Stocks of platinum metals in the hands of refiners, importers, and dealers were 322,843 ounces on December 31, 1941.

Stocks of platinum metals held by refiners [1] in the United States, December 31, 1937–41, in troy ounces

Year	Platinum	Palladium	Iridium	Osmium, rhodium, and ruthenium	Total
1937	60,236	21,942	8,846	8,475	99,499

1940 [1]	144,302	93,244	32,368		269,914
1941 [1]	150,887	138,014	33,942		322,843

[1] In 1940 figures also include stocks held in the United States by importers from the United Kingdom; in 1941 figures also include stocks held in the United States by all importers and dealers.

FOREIGN TRADE [4]

Imports.—Imports of platinum metals into the United States during 1941 established a new record and amounted to 309,995 ounces, a gain of 58 percent over 1940 and 1 percent over the previous peak year 1939. The principal sources of imported platinum metals in 1941 were Canada (217,909 ounces), United Kingdom (52,377 ounces), and Colombia (36,875 ounces). Imports of unrefined platinum (excluding scrap) increased phenomenally to 226,951 ounces in 1941 from 58,320 ounces in 1940, whereas imports of refined platinum (including scrap) declined to 27,763 ounces in 1941 from 68,376 ounces in 1940. Although receipts of iridium advanced to 1,292 ounces in 1941 from 237 ounces in 1940, they fell far short of the imports during the 5 years 1935–39, which averaged 4,354 ounces. Imports of osmiridium dropped to 266 ounces in 1941 from 1,857 ounces in 1940 and from an average of 3,380 ounces during the 5 years 1935–39. Imports of osmium and ruthenium increased 4 and 118 percent, respectively, over 1940, but palladium and rhodium decreased 23 and 22 percent, respectively.

[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Platinum metals imported for consumption in the United States, 1937–41

Year	Troy ounces	Value	Year	Troy ounces	Value
1937	206,937	$7,418,364	1940	195,645	$5,748,005
1938	161,189	4,366,912	1941	309,995	7,143,612
1939	306,627	9,881,531			

Platinum metals (unmanufactured) imported for consumption in the United States, 1940–41, by metals

[1] Less than 1 troy ounce.

Exports.—Exports of unmanufactured platinum metals declined phenomenally to 15,405 ounces in 1941 from 55,027 ounces in 1940 and from an average of 48,746 ounces during the 4 years 1936–39. The shipment of 8,100 ounces to U. S. S. R. in 1941 was refined platinum from stock held by the Amtorg Trading Corporation. Except for U. S. S. R., Canada (3,041 ounces) and Argentina (1,577 ounces) were the chief foreign markets for unmanufactured platinum metals in 1941.

Platinum and allied metals exported from the United States, 1937–41

[1] Figures for 1940 in Minerals Yearbook, Review of 1940, p. 739, should read—Manufactures of, except jewelry: China, 7 ounces, $322; Japan, 522 ounces, $27,697. No change in grand totals.
[2] Not separately classified before January 1, 1941.

WORLD PRODUCTION

Because of Government restrictions in many countries on the publication of statistics, few figures for 1940 and 1941 are available. However, data on world production of platinum metals by countries are fairly complete for 1936, 1937, 1938, and 1939; they are shown in Minerals Yearbook, Review of 1940, page 739.

Canada.—Figures are not available on the recovery of platinum metals from the nickel-copper ores of the Sudbury district, Ontario, in 1940 and 1941, but 148,877 ounces of platinum and 135,402 ounces of other platinum-group metals were recovered in 1939. Concentrates from the Port Colborne and Copper Cliff refineries and residues from

the Clydach (South Wales) refinery are normally shipped to the International Nickel Co. precious metals refinery at Acton, England, for recovery of platinum, palladium, iridium, rhodium, and ruthenium. Since 1940, however, much of the concentrates has been shipped to the United States for refining.

Colombia.—The South American Gold & Platinum Co. produced 30,548 ounces of crude platinum metals in 1941 (24,294 in 1940) and 72,582 ounces of gold (58,462 in 1940). The figures for other operators are not available.

In accordance with Decree 796, issued March 27, 1942, by the Colombian Government, all platinum production in Colombia must be sold to the Bank of the Republic.

Union of South Africa.—The estimated content of the platinum metals (exclusive of osmiridium) produced in the Union of South Africa was 71,975 ounces in 1940. Figures for 1941 are not available, but according to the South African Mining and Engineering Journal [5] "the report of Rustenburg Platinum Mines for the 12 months ended 31st August discloses that production to the full capacity of the plant proceeded uninterruptedly during the year, and the output in the form of crude platinoids and matte was dispatched to England for treatment."

MINOR METALS

By Allan F. Matthews [1]

SUMMARY OUTLINE

GENERAL STATEMENT

Initiation of a $7,750,000 project to make the United States self-sufficient in ilmenite supplies, subjection of virtually all metals to various degrees of Government control, and greatly increased production and consumption were the 1941 highlights of the metals regularly reviewed in this chapter. Calcium-silicon and titanium pigments were the only derivatives of the minor metals placed under priority order by the Office of Production Management in 1941 and early 1942. Titanium pigments were also subject to price control by the Office of Price Administration. On the other hand, most of the minor metals were under export control—specifically beryllium, cerium, columbium, radium, tantalum, thorium, titanium, uranium, and zirconium. On December 28, 1941, in accordance with Office of Production Management Order M-63, the Metals Reserve Co., subsidiary of the Reconstruction Finance Corporation, assumed control of all imports of rutile and zircon.

BERYLLIUM

Annual world production of beryl is estimated to have increased from 500 short tons in 1935 to 1937 and 1,000 tons in 1938 and 1939 to 2,500 tons in 1940. Appreciable advances in output were also registered during 1941. The principal sources of beryl are Argentina and Brazil. The United States, Germany, and Italy are the outstanding producers of beryllium metal, alloys, and compounds, but some output has been reported in France and Japan. The Axis Powers in recent years have acquired more than one-third of the beryl available in world markets. Beryllium alloys have many very desirable properties, and they are being utilized in ever-increasing quantities, but the trend is restricted by relatively high price and skepticism in some quarters as to the adequacy of ore reserves. Because of the highly refractory nature of beryl, the extreme reactivity of the metal at elevated temperatures, and the number of process steps

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

required, metallic beryllium is produced with a low over-all efficiency.[2] However, increased consumption in those applications where it is superior to other alloys will do much to lower the price. The mineralogical occurrence of beryl in pegmatite dikes is extremely common, but it is always sporadic and in no instance has been found to have continuity like ores in a vein. The current output is handcobbed by low-paid labor or is recovered as a none-too-remunerative byproduct. The quantities of beryl obtained in this fashion have supplied the demand adequately to date, and the output can doubtless be expanded. Larger tonnages of beryllium may prove to be extractable economically from low-grade beryl ores amenable to flotation or possibly from other beryllium minerals rarer than beryl but less sporadic in individual deposits. Interest was aroused during 1941 in a helvite deposit discovered recently in New Mexico.[3]

Domestic production.—Mine shipments of beryl since 1937, when the Bureau of Mines began to collect data on this ore, are shown in the accompanying table. Shipments in 1941, 31 percent greater than in 1940, were the largest on record. Beryl is produced in several Western and New England States as a byproduct in the mining of feldspar, mica, and other pegmatite minerals. Pennington and Custer Counties in the Black Hills of South Dakota contributed 96 percent of the United States total in 1941, compared with 61 percent in 1940. Beryllium metal, alloys, and compounds are produced by the Beryllium Corporation of Pennsylvania, Temple (near Reading), Pa., and by the Brush Beryllium Co., Cleveland, Ohio. Beryllium oxide is produced by Clifton Products, Inc., Painesville, Ohio. A plant for the manufacture of beryllium oxide and carbonate was being erected during 1941 at Harbor City, Calif., by the Calloy Co.

Beryllium ore (beryl) shipped from mines in the United States, 1937–41

Year	Mine shipments			State
	Short tons	Value		
		Total	Average per ton	
1937	75	$1,640	$21.87	Colorado, Maine, South Dakota.
1938	25	770	30.80	Maine.
1939	95	2,720	28.63	Colorado, Maine, South Dakota.
1940	121	3,721	30.75	Do.
1941	158	7,300	46.20	Maine, New Hampshire, South Dakota, Wyoming.

Foreign trade.—Beryl imports into the United States have mounted steadily to 1,635 short tons in the first 9 months of 1941. Imports in recent years, by country of origin, are shown in the accompanying table. United States concessions in the reciprocal trade agreement with Argentina, effective November 15, 1941, included a reduction in the duty on beryllium oxide and carbonate from 25 percent ad valorem to 12½ percent, although the older duty may be restored on 6 months' notice any time after the end of the present war. No beryl is exported by the United States, but beryllium-copper master alloys have been shipped to Great Britain for several years.

Beryl imported for consumption in the United States, 1937–41, by countries, in short tons

Country of origin	1937	1938	1939	1940	1941 (Jan.–Sept.)
Argentina	152	78	384	422	693
Brazil			75	377	942
India, British	30	58			
Union of South Africa		10		6	
Total:					
Short tons	182	146	459	805	1,635
Value	$8,031	$5,990	$14,574	$23,865	$77,680
Average per ton	$44.13	$41.03	$31.75	$29.65	$47.48

Price.—Domestic beryl, 10–12 percent BeO, was quoted nominally by the trade journals during 1941 at $30–$35 a short ton, f. o. b. mines, but actual prices obtained averaged over $45 a ton. Nominal quotations on imported beryl, c. i. f., by the American Metal Market were advanced on February 26 from $45–$49.50 to $47–$52 for 10–11 percent BeO and from $49.50–$54 to $52–$55 for 11–12 percent BeO, and the quotations remained at the new level throughout the remainder of 1941. The actual New York price on imported beryl containing 10–12 percent BeO is said to have been $50–$65 a ton during the early part of 1941 and $60–$72 in later months. Beryllium-copper, master alloy of 4 percent Be and remainder Cu, was priced unchanged at $15 per pound of contained Be, and metallic beryllium and beryllium-aluminum at $45 to $50 per pound of contained Be. Ceramic Industry quoted beryllium oxide, c. p., calcined at 1,350° C., at $4 a pound during 1941.

Beryllium-copper alloys.[4]—The outstanding use of beryllium today is in beryllium-copper alloys fabricated into springs, diaphragms, and motor parts subject to wear. These alloys generally contain about 2 percent beryllium and the remainder copper (although the beryllium content ranges from 0.1 to 3.5 percent), and 0.13 to 2.60 percent cobalt, chromium, or silver is often added. Beryllium hardens copper and increases its tensile properties without greatly decreasing electrical conductivity. Parts subject to wear in airplane engines are absorbing the largest quantities of beryllium-copper at present. In such applications as tappet roller bushings, counterweight bushings, oil pressure-relief-valve seats, and spacing shims, and, in general, in heavily loaded bushings where the action is eccentric or reciprocating and in parts mating with hard steel and subject to extreme vibration or shock loading, beryllium-copper is reportedly giving excellent service. Beryllium-copper springs have a large amplitude of movement combined with remarkable freedom from hysteresis or elastic drift—properties that enable them to possess and retain stable springiness to a much greater degree than springs made of any other available corrosion-resisting material. The dependability of these springs has prompted their use in sensitive altimeters, air-speed indicators, and a wide range of aircraft instruments, as well as in pressure gages, electrical contacts, business machines, camera shutters, telephone jacks, and radio equipment.

As beryllium-copper is nonmagnetic and has structural properties comparable to good alloy steels, it is used in parachute harness fasteners

[4] Stott, Louis L., Work cited in footnote 2. 10 pp. Beryllium—Its Present Field and Possible Future Applications. Steel, vol. 109, No. 17, October 27, 1941, pp. 62–64, 92–93.

and release springs to avoid magnetic disturbance of instruments. The alloy has a further advantage of nonsparking. Beryllium-copper hammers, wrenches, crowbars, chisels, and other tools are utilized in munition factories, petroleum refineries, and other plants where a spark from working steel against steel might ignite inflammable fumes or materials. Another interesting property of beryllium-nickel-copper alloys is illustrated by tests reported to indicate that the alloy is about 50 times more resistant to heat-checking than conventional nickel cast irons under frictional contact with materials used for brake blocks and clutch facings.

Other beryllium alloys.—Small additions of beryllium to nickel are said to impart physical properties even superior to those that can be obtained in the copper-base alloys. Interest in these alloys seems to have been centered in Europe, but small quantities of nickel containing 1.8 to 2 percent beryllium were produced in the United States during 1941. Beryllium-nickel has a very unusual combination of high tensile strength (270,000 p. s. i.) and elongation (8.8 percent in 2 inches). Applications to date include corrosion-resisting springs, springs subject to moderately high temperatures, hypodermic needles, and surgical instruments.

As beryllium has a low specific gravity (1.85), being only slightly heavier than magnesium (1.74) and 30 percent lighter than aluminum (2.70), it is being considered as a constituent of light metal alloys. Beryllium does not appear to alloy with magnesium, but industrial research on beryllium-aluminum is showing progress. Additions of 25–50 percent of beryllium greatly stiffen aluminum; and an alloy of this composition, called beralite, is being developed by Cooper-Wilford Beryllium, Ltd., Philadelphia, Pa. Beralite is said to be lighter than and as strong as duralumin, to have fatigue strength superior to that of any existing aircraft metals, and to have enough workability to be considered for aircraft forgings.[5] Suggested applications are in aircraft pistons, connecting rods, valve-actuating mechanisms, and certain air frames, such as control surfaces. Sawyer [6] compares beryllium-aluminum with standard aluminum-base aircraft alloys and states that, while higher modulus of elasticity greatly favors beryllium-aluminum alloys, this factor cannot overcome the disadvantage of inferior tensile strength where ductility is important. Addition of other components probably can improve low creep strength and other properties. The above statements, the author cited points out, concern properties at room temperature; at 600° F. (as may exist in a piston) beryllium-aluminum alloys have higher endurance limits and much higher tensile strength than the materials now in use and therefore hold out attractive possibilities if such parts can be made. A factor that has retarded development of beryllium-aluminum is the high price of metallic beryllium. Beryllium contained in aluminum alloy costs three times as much per pound as it does in copper or nickel, because it must be added to aluminum as pure metal, whereas it is introduced directly into copper and nickel as the less expensive oxide.

Beryllium has been used as a ferro-alloy in Germany, particularly, it is said, in armor plate and in a high-speed tool steel containing 12 percent Cr, 5 percent Ni, and 1 percent Be. Surface saturation of steel

[6] Sawyer, C. B., Beryllium as a Light Metal Component: Metals and Alloys, vol. 14, No. 1, July 1941, pp. 37–39.

by beryllium diffusion, a method somewhat analogous to sherardizing, greatly increases hardness. Additions of 1 to 2 percent of beryllium to various steels improve hardness, tensile strength, and acid resistance.

Beryllium metal and compounds.—Utilization of metallic beryllium has been limited principally to X-ray tubes, where small quantities of the metal are useful because of its transparency to X-rays. The second most important use of beryllium, quantitatively, is in white fluorescent lamps and fluorescent screens, where an oxide of high purity, containing less than 0.002 percent iron, is specified for the preparation of zinc-beryllium silicate. Beryllium oxide and beryllium carbonate, activated by uranium salts or rare earths, are utilized in luminescent paints. Pure beryllium oxide melts at 2,570° C.—550° C. higher than the melting point of alumina—and thus makes a good refractory. The washability of a new English textile made from seaweed is improved by treating it in a coagulating bath of beryllium acetate. Experiments indicate that beryllium carbonate may be a useful antirachitic substance.[7] It is reported that in recent years some 50 to 100 tons of raw beryl have been ground annually for use in ceramics.

Technologic developments.—Factors to be considered in exploring for peryl are outlined by Brinton.[8] In the course of its flotation investigations, the Bureau of Mines [9] found that a low-grade Nevada beryllium ore containing 1.3 percent BeO could be concentrated (using oleic acid as the collector reagent and Du Pont 23 as a frother) to material containing 5.5 percent BeO, representing 87 percent recovery of beryllium in 20 percent of the feed. When these flotation concentrates were dried and treated in a high-intensity magnetic separator, the nonmagnetic product contained 6.6 percent BeO in one-third the weight of the feed, but only half of the beryllium was recovered.

WORLD PRODUCTION

Production of beryl by various countries in recent years, insofar as data are available, is shown in the accompanying table.

World production of beryl, 1935–40, by countries, in metric tons [1]

Country [1]	1935	1936	1937	1938	1939	1940
Argentina	189	300	260	753	299	520
Australia, Western					6	2
Brazil (exports)		4		203	276	1,472
Canada (estimate)		18	18	9	161	(2)
India, British	126	89	24	15	8	(2)
Madagascar (estimated exports)	10	10	2	2	(2)	(2)
Portugal	2	2	21	(2)	(2)	(2)
Union of South Africa (estimate)	80	5	(2)	(2)	(2)	(2)
United States (mine shipments)	(2)	(2)	68	23	86	110

[1] In addition to countries listed, beryl may also be produced in France, Italy, Norway, Rumania, and U. S. S. R.
[2] Data not available.

Argentina.—Beryl is mined in the Provinces of Cordoba and San Luis. In previous years, the material has been exported only as raw beryl, but in 1941 a portion of the output was converted to beryllium

oxide-carbonate by the Sociedad Anonima Berilo Argentina in a new plant at Juan Ortiz, Province of Santa Fe.

Canada.—The property of Canadian Beryllium Mines & Alloys, Ltd., in Lyndoch Township, Ontario, was idle throughout 1941, but a shipment of ore to Kansas City, Mo., for testing a new reduction process was reported.[10] Mobirk Beryllium Mining Co., Ltd., did some development work on beryl deposits in the Winnipeg River district of Manitoba.

CALCIUM

Calcium metal formerly was imported from France and Germany, but in 1939 the Electro Metallurgical Co. built a plant at Sault Ste. Marie, Mich., and later expanded the capacity to several times the maximum imported in any 1 year. Domestic consumption of calcium metal during 1941 appears to have been about twice that in 1940.[11] Imports of calcium metal and calcium-silicon in recent years are shown in the accompanying table. During 1941 calcium metal, 97–98 percent, ton lots, was quoted by Charles Hardy, Inc., New York, at $1.25 a pound for carrots and about $2.00 a pound for castings, although the price was $1.50–$5.00 a pound in smaller lots. Calcium-silicon was quoted by Canadian Metals & Metallurgical Industries at 13½–15½ cents a pound, f. o. b. Welland, Ontario, during the first 5 months of 1941, 15–17 cents from June to September, and 15½–17½ cents during the last quarter of the year. In the United States, calcium-silicon was subjected to direct allocation by Office of Production Management General Preference Order M–20, effective July 29, 1941, which was revised and extended to May 31, 1942, by General Preference Order M–20–a, issued November 29, 1941. It was stated that production of calcium-silicon can be expanded as needed but that it requires very large quantities of electric power.

Calcium metal and calcium-silicon imported for consumption in the United States, 1937–41

Year	Calcium metal			Calcium-silicon		
	Pounds	Value		Pounds	Value	
		Total	Average per pound		Total	Average per pound
1937	23,767	$10,087	$0.42	3,751,918	$205,173	$0.055
1938	41,299	16,144	.39	1,402,314	77,003	.055

Metallic calcium is utilized as a scavenger in steel and secondary aluminum, to produce magnesium castings and calcium hydride, and to harden lead. Calcium is used as a deoxidizer and final addition in obtaining particularly clean steels and in imparting better working properties to high-nickel-chromium steels. Calcium-silicon (28–35 percent Ca and 60–65 percent Si) and calcium-manganese-silicon are likewise employed for this purpose, although the unalloyed metal may

[10] Northern Miner, vol. 27, No. 39, December 18, 1941, p. 2.
[11] Jeffries, Zay, Rare and Precious Metals: Min. and Met., vol. 23, No. 422, February 1942, p. 69.

have specific effects. Ready combination with oxygen and nitrogen may be among these effects, but the formation of a different type of sulfide and change of the nature of the nonmetallic inclusions when calcium is added as a metal are said to be the major reasons for its use.[12] Additions of calcium up to 0.25 percent in some magnesium castings reduce the heat-treating time by permitting higher temperatures and result in an improved surface. Calcium sometimes is used for deoxidizing aluminum castings and reconditioning scrap aluminum,[13] but Stroup [14] does not favor this procedure and states that the presence of calcium in aluminum alloys containing copper causes definite lowering of strength in the solution heat-treated temper. Metallic calcium is a starting point in the preparation of calcium hydride, which is a reducing agent in the production of titanium, uranium, vanadium, and zirconium. Calcium has been used to maintain lead in the emulsified state in high-lead-copper alloys, and calcium as a substitute for antimony in the hardening of lead is a promising application of strategic importance. Lead containing about 0.1 percent of calcium has properties equal to antimonial lead for cable sheathing, roofing sheets, and the negative plates, connector links, grid heads, and terminal posts of storage batteries. At present calcium-lead is prepared directly, either by electrolytic deposition of calcium in the lead or by dissociation of calcium carbide in lead, but production of this alloy from metallic calcium is said to be simpler and may be generally adopted in future.

COLUMBIUM AND TANTALUM

Domestic production of tantalum ore was resumed on a small scale in 1941. During the first 9 months of the year, columbium ore was imported at a considerably higher rate than during 1940, but entries of tantalum ore were lower. The Fansteel Metallurgical Corporation, North Chicago, Ill., a principal consumer of tantalite, was reported to have a 2-year supply of the ore at the end of 1941.[15] Mine shipments and imports in recent years are shown in the accompanying table. During the first 9 months of 1941, Nigeria supplied all the colum-

Tantalum ore shipped from mines and columbium and tantalum ores imported for consumption in the United States, 1937–41

Year	Mine shipments of tantalum ore		Imports			
			Columbium ore		Tantalum ore	
	Pounds	Value	Pounds	Value	Pounds	Value
1937	16,307	$13,317	922,654	$306,086	20,897	$40,742
1938	36,189	35,127	645,141	228,078	41,706	80,092
1939	340	200	109,132	37,062	56,561	82,990
1940			595,220	210,526	490,460	258,514
1941 [1]	250	[2] 280	983,495	348,087	276,968	126,282

[15] Wall Street Journal, vol 118 No 153, December 30, 1941, p. 8

bium ore imported except about 5,000 pounds from Argentina and Brazil combined; of the imports of tantalum ore in the same period, 53 percent came from Belgian Congo, 35 percent from Brazil, and 12 percent from South Africa. Brazilian exports of tantalum ore during this period totaled 63 short tons, of which 59 percent was shipped to the United States.

Price.—Columbium ore is not quoted in the trade journals, but imports containing about 65 percent Cb_2O_5 have been valued at about 35 cents a pound in recent years. Tantalum ore (60-percent concentrates) has been listed by Metal and Mineral Markets at \$2.00–\$2.50 per pound of contained Ta_2O_5. Imported tantalum ore dropped in average value from \$1.47 a pound in 1939 to 53 cents in 1940 and 46 cents in 1941, probably owing to an increase in columbium content. Most of these ores are mixtures of columbite and tantalite, but the most desirable ores are high in one mineral and low in the other. Ferrocolumbium, 50–60 percent, was quoted throughout 1941 at \$2.25–\$2.35 per pound of contained Cb, f. o. b. Niagara Falls, N. Y. Columbium metal was quoted at \$227–\$254 a pound and tantalum metal at \$65–\$73 a pound.

Uses of columbium.—The addition of about 0.5 percent columbium to chrome steels improves weldability by inhibiting intergranular corrosion, reduces air-hardening, and increases oxidation resistance, creep strength, and impact strength, regardless of heat treatment. Aircraft exhaust stacks, manifolds, and collector rings are made of stainless steels containing about 0.8 percent columbium. Seybolt [16] found that 0.58 percent columbium brings the softening temperature of cold-rolled copper from 250° C. up to about 450° C. and that 0.29 percent brings the softening temperature of 80–20 cupronickel from 500° C. up to about 550° C. Iron containing 3 percent columbium is suitable for high-pressure steam turbines operating at temperatures exceeding 1,000° F. Columbium is a constituent of an aluminum alloy known as ceralumin,[17] which is said to be used quite widely in British aircraft. The addition of columbium to a chromium-aluminum-iron electrical resistance wire overcomes the detrimental effect of carbon on the life of elements built of such wires.[18]

Uses of tantalum.—Ultrahard cemented carbides of tantalum are being used increasingly—alone or in combination with carbides of tungsten or titanium—in wire-drawing dies, steel-cutting tools, and wear-resistant parts of machines. Large dies for cold-nosing artillery shells are among such uses. A cast alloy containing tantalum, columbium, and tungsten ("Tantung G"), which has a hardness approaching that of the hard carbides, plus much higher strength and toughness, is being used to increase production upon older machines not suited for employing cemented carbides. Tantalum metal has a variety of applications, of which perhaps the most important quantitatively is in the manufacture of corrosion-resistant equipment for chemical plants and laboratories. Tantalum metal is used in radio tubes, lamp filaments, neon tubes, electrolytic cathodes, surgical and dental instruments, heat interchangers, pump and valve parts, nozzles, spin-

nerets for synthetic textiles, temperature-control apparatus, electrical contacts, and lightning arresters for railway-signal circuits. Tantalum oxide is a component of a glass having a very high refractive index and low dispersion—factors that permit the manufacture of superior aerial camera lenses which are thinner and have less curvature. Sun and Silverman [19] studied glasses containing 5 to 36 percent tantalum oxide.

INDIUM

Augmented production of engine bearings and war-inspired restrictions on ordinary plating metals stimulated interest in indium during 1941. Indium is recovered as a byproduct of zinc and lead operations by the American Metal Co., Ltd., American Smelting & Refining Co., Anaconda Copper Mining Co., and National Zinc Co., Inc. Domestic production could be increased to more than 40,000 pounds annually, according to William S. Murray, president of the Indium Corporation of America.[20] In Mohave County, Ariz., the Indium Corporation of America has a property said to contain 35,000 tons of ore averaging about 2 ounces of indium per ton.[21] However, demand for the metal has not yet become sufficient to justify exploitation of this property, particularly in view of the ability of zinc refineries to supply ample quantities. Abroad, indium has been produced commercially in Germany, Belgium, and possibly Japan and U. S. S. R.

Price.—In December 1940 the price of metallic indium, as quoted in the trade journals, was reduced from $15 to $12.50 per troy ounce, where it remained throughout 1941.

Uses.—Indium is deposited on and alloyed with cadmium-nickel and copper-lead on bearings for airplane, automobile, and Diesel engines to resist the corrosive action of lubricants containing organic acids. After the nonferrous coating is applied to the ferrous base, an indium layer 0.001 to 0.0005 inch thick is plated on the undercoat and diffused through it at about 175°–180° C. to form a protective alloy surface containing 0.2 to 4 percent indium. Coatings of indium, alloyed with lead, copper, cadmium, zinc, silver, or gold, have been suggested for washers, contact points, light reflectors, molds for plastics, decorative metal strips, collapsible tubes, cosmetics containers, jewelry, and office machinery. Indium has been used to prevent corrosion by perspiration of the small pins in the hinges of spectacle frames. A steel article coated with a 4½-percent indium-lead alloy is reported to have successfully resisted severe exposure to salt spray. Indium-alloy coatings are easily polished and burnished.

In addition to plating, 0.5 to 5 percent indium is used in dental alloys, where it is said to impart superior compressive strength and resistance to tarnish. Indium is an advantageous constituent of certain low-melting alloys and has recently been found to improve the "wetting" properties of brazing materials through a wide range of melting points. The use of indium in pharmaceuticals and as a mordant for the dyestuffs industry is being developed.

RADIUM AND URANIUM

The Eldorado mine at Great Bear Lake, Northwest Territory, Canada, operated by Eldorado Gold Mines, Ltd., and the mine in Belgian Congo, operated by Union Minière du Haut Katanga, which together yield nearly the entire world output of radium-uranium ore, were both inoperative during 1941. The Canadian company, however, experienced in 1941 its best sales year to date, and its refinery at Port Hope, Ontario, is now operating on a 24-hour basis. Large ore stocks at the refinery are being cleaned up, and the mine at Great Bear Lake will resume production in 1942. Mining operations in Belgian Congo were halted as a result of the German invasion of Belgium in May 1940 and the consequent unavailability of refining facilities at Oolen, near Antwerp. In general, the United Nations are in a comparatively favorable position as regards radium and uranium. It is estimated that these countries possess two-thirds of the world radium supply and three-fourths of the uranium and, furthermore, control well over 95 percent of all the known ore reserves. Of the stocks held at Oolen, all of the radium and part of the uranium were removed from Belgium before the invasion and shipped to the United States. The Oolen refinery was not damaged, but the Germans apparently have not attempted to operate it on the basis of the small amounts of ore obtainable from St. Joachimsthal in Czechoslovakia and other European localities. The agreement between Union Minière du Haut Katanga of Belgium and Eldorado Gold Mines, Ltd., of Canada, dividing world markets for radium in a 60 : 40 ratio, was dissolved in 1941.

Domestic production.—Radium, uranium, and vanadium are recovered from carnotite ore mined in western Colorado and eastern Utah. The two radium producers in the United States are the Vitro Manufacturing Co., Pittsburgh, Pa., which had an output of 3 grams in 1941 and expects to supply 3 to 5 grams in 1942, and the S. W. Shattuck Chemical Co., Denver, Colo., which produced about 225 milligrams in 1941 and anticipates an output exceeding 1 gram in 1942.

Foreign trade.—Imports of radium salts, radioactive substitutes, and uranium ore and compounds are shown in the accompanying table. All of the imports during the first 9 months of 1941 were from Canada, except that 21 percent of the uranium compounds came from Belgian Congo.

Radium salts, radioactive substitutes, and uranium ore and compounds imported for consumption in the United States, 1937–41

Year	Radium salts			Radioactive substitutes (value)	Uranium ore		Uranium oxide and salts	
	Grams	Value						
		Total	Average per gram		Pounds	Value	Pounds	Value
1937	15 29	$377,659	$24,700	$711			203,473	$258,417
1938	38 75	787,025	20,300	5,746			376,708	520,540
1939	78.631	1,953,820	24,800	966	5	$10	1,439,324	1,197,786
1940	30.311	748,097	24,700	5,650	2,400,198	2,110,927	240,199	388,355
1941 (Jan.-Sept.)	4.063	101,480	25,000	13			229,872	345,264

Price.—In 1941 the market price of radium dropped from $30 a milligram to $25, and even lower. Individual sales at less than $20 a milligram were reported. Prices quoted at the end of 1941 by the Radium Chemical Co., Inc. (sales agent in America for Union Minière du Haut Katanga), were as follows: $23 a milligram for 1–99 milligrams, $21.50 for 100–499 milligrams, and $20 for 500 milligrams or over. Throughout 1941, Ceramic Industry listed uranium oxide at $1.75–$3.00 a pound; and Glass Industry quoted yellow or orange uranium oxide at $1.65 a pound, black uranium oxide at $2.55 a pound, and orange or yellow sodium uranate at $1.65 a pound.

Uses of radium.—The principal use of radium is in the treatment of cancer and skin diseases, but the war program is drawing on increasing amounts for luminous paints and industrial radiography. Clocks, gun sights, compasses, and various other types of instrument dials are coated with radium compounds to permit them to be seen under blackout conditions. Radium is used to detect flaws in castings, forgings, and welds of numerous kinds of metals and alloys. Aircraft parts hull castings, valves for power plants and refineries, cast piping, welded pressure vessels, gun carriages, turret tracks, shaft struts for ships, frogs for railroads, and turbine casings are among the equipment inspected in this way. From 25 to 1,000 milligrams of radium (usually 100 to 200 milligrams) in the form of radium sulfate in a duralumin container are ordinarily placed in the center of a circle of articles to be tested. X-ray films are fastened to the backs of the specimens, and the penetrating gamma rays cause a shadowgraph to appear upon the film very similar to one obtained with X-rays. Defects as small as 0.25 percent of the thickness of the article, ranging from ⅛ to 10 inches, can clearly be seen. Magnification of the images to 5 and 10 diameters reveals defects otherwise unnoticed. Radiographic inspection of magnesium-alloy castings was described in some detail by Bailey.[22] Some of the recent literature on industrial radiography has been summarized.[23] Progress in radiography prompted organization in October 1941 of the American Industrial Radium and X-ray Society, Inc. The primary aim of the society is to promote scientific education in industrial radiography; headquarters will be in Chicago.[24] A new use of radium is as a radium-beryllium salt in geophysical exploration for petroleum.

Figures showing radium transactions are not available, but preparations tested each year by the National Bureau of Standards, under the supervision of Dr. L. F. Curtiss, give some idea of movements. Such preparations included 9.0 grams of radium in 1937, 10.5 in 1938, 22.0 in 1939, 16.8 in 1940, and 19.9 in 1941.

Radon, polonium, and mesothorium.—Useful radiation from radium is not due to the radium itself but rather to its disintegration products. Radium first decomposes into the gaseous element radon (atomic number, 86). Radon is put in tubes and used in both hospitals and industrial plants. It loses its effectiveness after a few days, but in some circumstances this short life is advantageous. Radiologists in Great Britain were temporarily forced by German bombers to abandon most of their clinical work with radium because of the danger of losing

[22] Bailey, P. M., Radiography—Applied to Magnesium Alloy Castings: Metal Ind., vol. 59, No. 15, October 10, 1941, pp. 232–235.

[24] Steel, Industrial Radium, X-ray Society Formed: Vol. 109, No. 18, November 3, 1941, p. 59.

it. In its place, hospitals were supplied with radon, individual losses of which would not be significant. The radon tubes were filled in subterranean plants, one of which was financed with $25,000 cabled to London by the British War Relief Society in the United States.[25] Polonium is a radioactive element (atomic number, 84) recovered at the Port Hope refinery and used in minute traces in spark-plug electrodes to ionize the air gap and speed the passage of a hot spark under all temperature conditions, even when the battery is low. Made by the Firestone Tire & Rubber Co., the nickel electrodes either are coated with a film of polonium or contain 0.000000001 percent polonium as an alloy. The longer the radioactive spark plug is used, the more efficient it becomes.[26] Mesothorium is a radium isotope (atomic numbers, 88 and 89) which is used as a substitute for radium. It is obtained from monazite-sand residues and is more radioactive than radium itself. The principal application at present is probably in black-out paints. The number of mesothorium specimens tested annually by the National Bureau of Standards gives some index as to demand. Such specimens contained 1,026 milligrams in 1934, 300–600 yearly in 1935–38, 49 in 1939, and 301 in 1940 and reached a high of 1,451 in 1941.

Uses of uranium.—Uranium is now used principally in ceramics, luminescent paints, tool steels, and chemicals. Uranium oxides color pottery glazes and porcelain bodies black, gray, brown, or green in a reducing environment and yellow, orange, or red under oxidizing conditions. They are sometimes used as a crystallizing agent in crystalline glazes. Sodium uranate and sodium uranyl carbonate produce the fluorescence typical of uranium glasses, which are yellowish green in transmitted light and emerald green in reflected light. These compounds under other conditions color glass yellow, orange, or red.[27] Uranium salts are incorporated in luminescent paints, either for their own inherent fluorescence or as an activator for such accessory compounds as zinc-cadmium sulfide and beryllium oxide. Uranium imparts desirable properties to tool steels. The metal is introduced as ferrouranium or, more recently, as a master alloy containing 66 percent uranium and 33 percent nickel. Stainless silverware can be made by plating the ware in an electrolytic bath containing silver fluoride and compounds of uranium and tin. Uranium oxides are used as catalysts in a number of organic chemical reactions.

SELENIUM AND TELLURIUM

Production of selenium and of tellurium in the United States in 1941 increased 89 and 162 percent, respectively, and sales showed corresponding gains. Producers' stocks of both metals declined during the year. Selenium imports (all from Canada) expanded. Salient statistics for 1937–41 are shown in the accompanying table. Canada increased its production of selenium and tellurium during 1941, and the Germans are said to have brought into operation a new selenium plant in the Mansfeld copper district.[28] The base price of selenium (black, powdered, 99.5 percent) and of tellurium continued to be

[2] Includes selenium salts.
[3] Figures cover January to September, inclusive.

Selenium, in conjunction with cadmium, is important as a red colorant in ruby glasses for signal lenses, tail lights, fire globes, and tableware. Antithetically, selenium acts as a decolorizer; 0.8 ounce per ton of glass imparts a pink that cancels the green from iron impurities and thereby yields a virtually colorless product. Increasing quantities of selenium are used in rectifiers and light-sensitive cells and for flameproofing wire and cable insulation. Additions of selenium or tellurium have been found to increase the ductility of nickel-manganese steels and to improve machinability of stainless steels and copper alloys. Augmented demand for tellurium is principally as a carbon stabilizer in cast iron. Tellurium is also called upon to toughen lead [29] and rubber. Tellurium-lead work-hardens and is resistant to acids, even at high temperatures.

TITANIUM

Soon the United States will attain self-sufficiency in another mineral—ilmenite—through development of the Adirondack titaniferous magnetite deposits, which was begun in 1941. The project was born of the necessity to discontinue the practice of importing several hundred thousand tons of ilmenite annually from India. Such cargo space was needed for the transportation of other ores more directly essential to the victory program. Rutile from Australia faced a somewhat more fortunate situation, for ships delivering war supplies in the South Pacific loaded ores for the return voyage. Titanium pigments were in great demand during 1941. The Navy is said to have purchased about 2,500 tons in that year, and individual orders of 300 tons for aircraft camouflage lacquer and 350 tons to paint the interior of a single airplane plant were reported.[30] Such military requirements prevented the paint industry from obtaining much more than 60 percent of its needs for civilian consumption and forced manufacturers to use less titanium dioxide and more white lead.[31] Titanium pig-

[31] Business Week, No. 637, November 15, 1941, pp. 42, 44–45.

ments were put under allocation by Office of Production Management General Preference Order M–44, effective December 1, 1941. Subsequent amendments moved the effective date to January 1, 1942, clarified the original text, and increased from 20 percent to 25 percent (effective February 1, 1942) the proportion of titanium pigments that had to be set aside by producers for direct allocation by the War Production Board. No price action on titanium pigments was taken during 1941, but to stem a proposed advance the Office of Price Administration, on January 2, 1942, requested the stabilization of prices at levels of October 1, 1941, and 2 months later made the informal request mandatory by issuing Price Schedule 98, effective March 1, 1942.

Domestic production.—Ilmenite and rutile were produced in Arkansas, Florida, and Virginia during 1941, mining of ilmenite in North Carolina was begun early in 1942, and plans were made to work titanium ore near Elma, Wash. The Bureau of Mines is not at liberty to publish figures showing domestic production of titanium ores. Ilmenite concentrates shipped from domestic mines in 1941 contained 42 to 54 percent TiO_2, and rutile concentrates contained 92 to 95 percent TiO_2. The geology of the Virginia titanium deposits was described in some detail by Ross.[32] The most significant feature of the 1941 titanium picture was the plan to exploit the Adirondack titaniferous iron ores. Mining will be begun in the summer of 1942, and at full capacity the project will enable the United States to be virtually self-sufficient in supplies of ilmenite. The property is being developed by the Titanium Division, National Lead Co., and the following details are abstracted from a comprehensive report by I. D. Hagar,[33] general manager.

In the Adirondack Mountains at Newcomb, Essex County, northeastern New York, a titaniferous iron-ore deposit, known as the MacIntyre Development, is being opened up by the National Lead Co. to obtain titanium for use in pigments. Purchased were some 7,000 acres, including the Sanford Hill deposit, located on the east shore of Lake Sanford, and the Iron Mountain deposit, about 1½ miles to the northeast. The National Lead Co. offered through the Office of Production Management to make a part of the output available to any pigment producer who would finance the requisite additional facilities. In this manner the Krebs Pigment & Chemical Division of E. I. du Pont de Nemours & Co., Inc., acquired an interest in the development and will receive one-fourth of the production for 10 years. The program of operation calls for a daily mine output of 5,500 long tons of ore analyzing 16 percent TiO_2, from which the mill will produce 800 long tons of ilmenite concentrates containing about 48 percent TiO_2. In addition, there will be a byproduct of approximately 1,800 tons daily of low-phosphorus magnetite. There is some question as to the ready marketability of this concentrate, since it will contain about 10 percent TiO_2, the effects of which in a blast furnace constitute a controversial question. However, much interest is being expressed by various steel manufacturers in the possibility of utilizing this magnetite, in spite of the alleged handicap. Beginning in May 1941, a core-drilling program involved the extraction of over 11,000 feet of diamond-drill cores from 70 drill holes. Examination of these cores showed that there is available in the Sanford Hill deposit above lake level approximately 15,000,000 tons of ore analyzing 16 percent TiO_2. This quantity is estimated to constitute a sufficient supply for the domestic pigment industry for at least 10 years.

The mine will be of the open-pit or bench-type, utilizing churn drills and electrically operated shovels to load the broken ore on heavy-duty mine trucks for haulage to the mill. The mill will contain the following units: (1) The crushing plant, equipped with a 48- by 60-inch jaw crusher, a 5½-foot standard cone

crusher, a 5½-foot shorthead cone crusher, and attendant screens and conveyors. (2) The wet mill, which will contain the crushed-ore bins, 4 rod mills with attendant elevators, screens, and pumps, 12 Crockett wet-belt separators for separating the magnetite, 96 wet-concentration tables for separation of the ilmenite, and units for dewatering the concentrates. (3) The dry mill, in which is included a battery of steam coil driers, operated by two 500-hp. boilers, and 21 Wetherill dry magnetic separators. Cost of development is estimated at $7,750,000. Materials for the entire development were made available through the issuance by the Office of Production Management of a blanket A-1-c Preference Rating Certificate, one of the highest blanket priorities granted so far to a commercial enterprise not directly engaged in the manufacture of weapons.

Foreign trade.—Imports of titanium ore and ferrotitanium in recent years are shown in the accompanying table. Of the 139,944 long tons of ilmenite imported during the first 9 months of 1941, 95 percent came from British India, 3 percent from Canada, and 1 percent each from Brazil and Portugal. Imports of rutile during the same period, including the rutile in zircon-rutile concentrates from Australia, are estimated at 4,000 short tons—78 percent from Australia and 22 percent from Brazil. Exports of titanium pigments from the United States were 5,950 short tons during the first 9 months of 1941 and 3,592 in the corresponding period of 1940. Such exports totaled 4,962 tons in the 12 months of 1940 compared with 4,319 in 1939.

Titanium ore [1] and ferrotitanium imported for consumption in the United States, 1937–41

Year	Titanium ore				Ferrotitanium	
	Ilmenite		Rutile [1]			
	Long tons	Value	Short tons	Value	Pounds	Value
1937	153,993	$770,757	665	$67,643	4,500	$608
1938	209,174	1,018,403	230	26,533		
1939	255,872	1,126,200	442	23,170	350	77
1940	197,894	750,590	156	14,849		
1941 (Jan.-Sept.)	139,944	574,651	[1] 930	[1] 110,002		

[1] Excludes rutile in zircon-rutile concentrates from Australia, such imports are estimated at approximately 3,000 tons from January to September 1941

Prices.—Quotations for ilmenite, 50–60 percent TiO_2, at $18–$20 a long ton were replaced in February by prices of $28–$30 for straight 60-percent material, which held throughout 1941, according to Metal and Mineral Markets. Rutile, 88–90 percent TiO_2, advanced $10 in April to $95 a short ton, and 94-percent concentrates remained at 8–10 cents a pound during all of 1941. Titanium metal, 96–98 percent, was listed at $5–$5.50 a pound. Throughout 1941, Steel quoted ferrotitanum at $1.23 per pound of contained Ti for 40- to 45-percent grade and $1.35 for 20- to 25-percent grade, and ferrocarbontitanium, 15–20 percent Ti, at $142.50 a short ton for 6- to 8-percent carbon and $157.50 for 3- to 5-percent carbon. The base price of titanium dioxide was 13½–15½ cents a pound during the first half of 1941, according to Oil, Paint and Drug Reporter, but at the beginning of July was raised to 14½–16½ cents, at which level it was fixed by Price Schedule 98, previously noted.

Uses.—Most of the titanium supply is consumed as dioxide in paints, paper, rubber, leather, ceramics, plastics, linoleum, printing ink, textiles, cosmetics, soap, and welding-rod coatings; the remainder

goes into titanium ferro-alloys, hard-cutting alloys, other nonferrous alloys, and metallic titanium. Domestic production of titanium pigments has more than doubled since 1938 and, according to Chemical and Metallurgical Engineering, approached 165,000 short tons in 1939. Titanium white paints are noted for a high degree of opacity, reflectance, and durability. Titanium dioxide makes it possible to manufacture workable porcelain enamels with a higher degree of acid resistance than can be obtained by any other means; at the same time, a remarkable degree of opacity in developed and gloss is improved.[34] Ilmenite is the source of all titanium pigments and also enters into the production of alloys and welding rods. By far the largest use of rutile is as a flux in welding-rod coatings, where its function is to shield the arc from oxidation during welding and to produce a brittle slag, which protects the cooling weld deposit.[35] The second most important use of rutile is in steel manufacture, where ferrotitanium and ferrocarbontitanium act as strong deoxidizers (to some extent replacing aluminum) and as addition agents to inhibit intergranular corrosion of stainless steels and air-hardening of 5-percent chromium steels.[36] A new type of permanent magnet contains 6 to 12 percent titanium.[37] Rutile is also used in ceramics and a number of nonferrous alloys, particularly titanium-aluminum, which improves the grain of aluminum castings. Titanium carbide is a constituent of hard alloys used in machine tools. A comprehensive Russian technical article on this application has recently been translated.[38] The use of metallic titanium has been limited principally to radio tubes. Titanium deserves study as a structural material, although it is difficult to produce metal free from objectionable oxygen and nitrogen.[39] Traces of metallic titanium in mercury boilers inhibit corrosion and facilitate heat transfer. Titanium tetrachloride is utilized in smoke screens and in purifying aluminum alloys.

WORLD PRODUCTION

Australia.—Zircon Rutile, Ltd., Byron Bay, New South Wales, increased its production of zircon-rutile concentrates in 1941.[40] The International Titanium Corporation, controlled by the American Rutile Corporation and Ventures, Ltd., of Canada, began producing concentrates of rutile and zircon in New South Wales in June 1941 and shipping the material to Carteret, N. J., for further separation.[41] Titanium minerals and zircon are also being recovered from black sands at Lower Piper River near Low Head, on the northern coast of Tasmania.[42]

Brazil.—During the first 9 months of 1941, Brazil exported 2,621 metric tons of ilmenite and 1,462 metric tons of rutile. All the ilmenite and 57 percent of the rutile were shipped to the United States.

[1] Data not available.
[2] Exports.
[3] Bureau of Mines not at liberty to publish figures.
[4] Includes 72 tons of mixed rutile-ilmenite concentrates.

Canada.—Ilmenite production from St. Urbain, Quebec, increased in 1941. Other titaniferous iron deposits were being investigated and may contribute to the 1942 output.[43] Titanium pigment imports by Canada in 1940 totaled 3,069 short tons, principally from the United States.[44]

Norway.—Titanium deposits were reported discovered in Norway as a result of a systematic survey conducted by Norwegian and German geologists and engineers.[45]

ZIRCONIUM

Zircon is recovered from beach sands near Melbourne, Fla., by the Riz Mineral Co. as an accessory of titanium ore and from gravels near Lincoln, Calif., by the Fay Placers Mining Co. as a byproduct of gold dredging. Although domestic production reached 3,646 short tons in 1927, there was none from 1929 to 1939. The rate of output was small during 1940 and 1941 but was increased somewhat early in 1942. Some work was done on a zircon deposit in Wisconsin during 1941. Imports of zirconium ore and zirconium ferro-alloys in recent years are shown in the accompanying table. Entries of zirconium ore during the first 9 months of 1941 totaled 20,101 short tons—73 percent from Australia, 24 percent from Brazil, and 3 percent from British India. Some comments on the Australian properties may be found in the foregoing titanium discussion in this chapter. The Brazilian zirconium ore is essentially baddeleyite and has a ZrO_2 content (82 percent) approximately 1½ times that of Australian zircon. Melzer and Chambers [46] have described the deposits in Brazil.

Zirconium ore [1] *and zirconium ferro-alloys imported for consumption in the United States, 1937–41*

Year	Zirconium ore [1]		Zirconium ferro-alloys	
	Short tons	Value	Pounds	Value
1937	8,934	$129,576	230,449	$18,085
1938	2,093	62,138	244,126	13,520
1939	3,433	49,919	799,269	50,169
1940	16,845	252,749	533,055	37,126
1941 (Jan.–Sept.)	20,101	446,286		

[1] Includes zircon-rutile concentrates from Australia.

Price.—Throughout 1941, Metal and Mineral Markets quoted, unchanged from 1940, zirconium ore, 55 percent ZrO_2, at $60–$70 a short ton, f. o. b. Atlantic seaboard; zirconium ferrosilicon at $102.50–$107.50 a long ton for 12–15 percent Zr content and 14–16 cents a pound for 35–40 percent Zr; and powdered zirconium metal at $7 a pound. Ceramic Industry quoted crude zircon, pound basis, at 5–7 cents, refined zircon at 8–10½ cents, and zirconium oxide at 40–49 cents.

Uses.—The bulk of the zirconium is consumed in ceramics, chiefly in porcelain enamels and pottery glazes but also in electrical and chemical porcelains and heat-resistant glasses. The function of zirconium in enamels and glazes is opacification,[47] and this use conserves significant amounts of antimony, tin, and zinc. The second-largest use of zirconium is in refractories, particularly for glass-melting furnaces. Zirconium purifies, hardens, and strengthens steels and acts with aluminum to harden cupronickel. Metallic zirconium as powder or ductile metal is used in photoflash bulbs, radio tubes, ammunition primers, and welding rods. Zirconium compounds are important in tanning, and zircon sand is an advantageous foundry sand.

PART III. NONMETALS

BITUMINOUS COAL AND LIGNITE [1]

SUMMARY OUTLINE

SURVEY OF THE BITUMINOUS-COAL AND LIGNITE INDUSTRY IN 1941

Under the stimulus of increased industrial activity arising from the national defense program, coal requirements increased sharply in 1941, and production was the largest since 1929. During the first quarter production was high to fill orders by consumers for storage in anticipation of possible suspension of mining when the wage contract expired on March 31. Output was largely at a standstill during April pending the signing of a new wage contract.

Production.—The estimated output of soft coal in 1941 was 511,-290,000 net tons, an 11-percent increase over 1940. Following the trend of industrial activity, the production for 1941 was 65 percent above the record low of 1932 and only 4 percent below the 534,989,000 tons of 1929 (see figs. 1 to 3 and tables 2 and 3). The trend of average value is shown in table 18.

Consumption.—Each of the major classes of consumers used more coal in 1941 than in 1940, and the increase ranged from 119 percent for beehive coke ovens to 8 percent for byproduct coke ovens (see table 4).

[1] Data for 1941 are preliminary; detailed statistics with final revisions will be released later. Data for 1939 and 1940 are final.

The collection of statistics on the bituminous-coal industry which before 1937 was conducted by the Bureau of Mines is now performed by the Bituminous Coal Division, U. S. Department of the Interior, Dan H. Wheeler, Director.

Material in this chapter was prepared in the Division's Economics Branch under the supervision of G. A. Lamb, chief. It was completed under the immediate direction of W. H. Young, in collaboration with R. L. Anderson, M. E. McMillan, and R. M. McKinney. The figures for 1939 were compiled under a joint agreement between the Bureau of the Census and the Bituminous Coal Division.

Changes in stocks.—The reserve supply of coal in the hands of industrial consumers and in retail coalyards rose from a total of 50,998,000 net tons at the beginning of the year to 62,737,000 tons at the close. In spite of the increase in total tonnage, the days' supply of stocks advanced only from 38 to 40 because of the increased rate of consumption. Between the same periods, stocks on the upper Lake docks advanced 779,188 tons, whereas unbilled coal in cars at the mines or classification yards fell 378,600 tons (see fig. 1 and tables 1 and 5).

Mechanization.—Sales of mechanical loading equipment for use in bituminous coal mines, in terms of total capacity, increased 31 percent in 1941 over 1940.

Mechanical cleaning.—Sales of mechanical cleaning equipment during 1941 indicate a gain over earlier years in mechanically cleaned coal. The total capacity of cleaning plants sold in 1941 is estimated

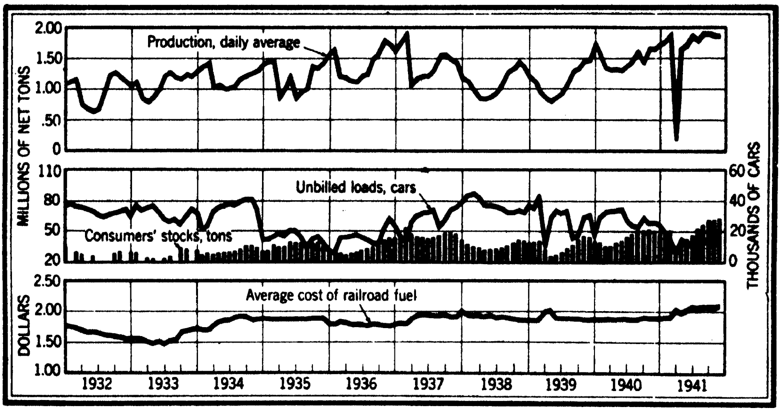

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal and lignite in the United States, 1932–41.

at 8,000 net tons of cleaned coal an hour (see Coal Age, February 1942, p. 66).

Trend of employment.—Estimates of the average number of men employed at bituminous coal and lignite mines in 1941 indicate a rise over the 1940 figure, which was 439,000. Indexes compiled by the Bureau of Labor Statistics upon the basis of a sample that includes more than half the workers in the industry show an increase of almost 4 percent in employment for 1941 over 1940 if normal operations during the April suspension are assumed in 1941. Reports from mining departments of several States also indicate a similar increase for the same period. These data suggest an estimate of 459,000 employees for 1941.

Trend of capacity.—The potential output upon a 308-day basis was 703,000,000 tons in 1940. Under the 5-day week, full-time operation is limited to approximately 261 days. The potential output of mines operating upon a 261-day basis was 595,000,000 net tons in 1940 compared with the total actual production of 460,771,500 tons.

Trend of fuel efficiency.—The upward trend in the efficient utilization of fuel in 1941 made some slight inroads into the coal market (see fig. 4 and table 6).

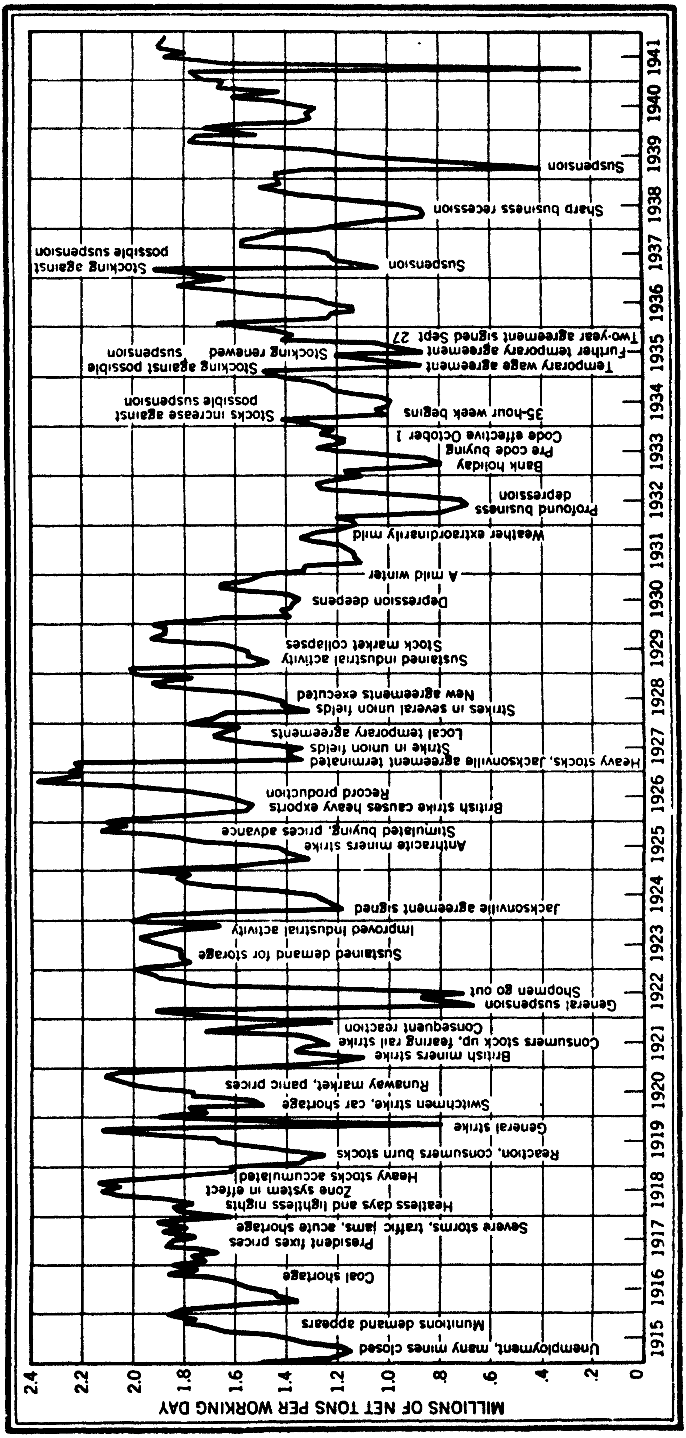

FIGURE 2.—Average production of bituminous coal and lignite in the United States per working day in each month, 1915–41.

Competition of oil and gas.—The competitive struggle of coal with oil and gas continued in 1941. The consumption of coal by railroads in 1941 increased 15 percent over 1940, but the consumption of oil by railroads increased 21 percent during the same period. Electric public utilities consumed 21 percent more coal and 21 percent more oil in 1941 than in 1940. The kilowatt-hours produced by water power at electric public utility power plants increased 7 percent in 1941 over 1940. (See figs. 5 to 7 and tables 7 to 9.)

In domestic heating comparable figures are available for mechanical firing equipment only. Sales of domestic stokers using bituminous

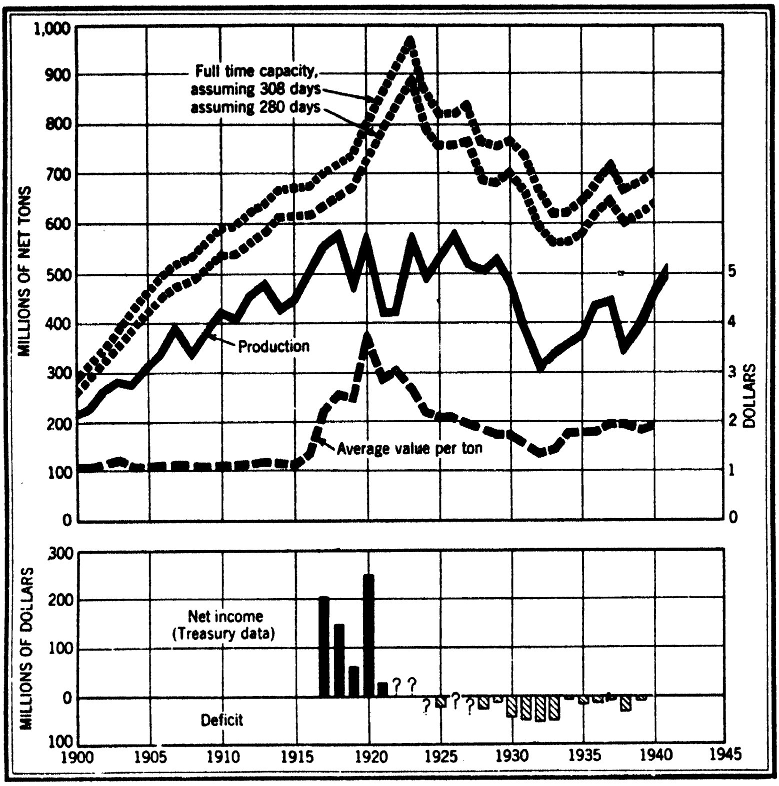

FIGURE 3.—Trends of bituminous coal and lignite production, realization, mine capacity, and net income or deficit in the United States, 1900–1941.

coal rose from 123,167 in 1940 to 158,734 in 1941, or 29 percent, whereas shipments of domestic oil burners and boiler-burner and furnace-burner units rose from 245,799 to 271,673, or 10 percent.

SOURCES OF DATA AND ACKNOWLEDGMENTS

Bituminous coal and lignite production statistics for 1941 are preliminary estimates prepared by the Bituminous Coal Division in accordance with standard procedure used in the past.

The 1939 statistics on bituminous coal and lignite were obtained through a survey conducted jointly by the United States Depart-

ment of Commerce, Bureau of the Census, and the United States Department of the Interior, Bituminous Coal Division.

The 1940 bituminous coal statistics were compiled by the Bituminous Coal Division and the 1940 lignite statistics by the Bureau of Mines.

Final production of bituminous coal and lignite for 1940 was 460,771,500 net tons. This differs slightly from 461,318,629 tons, as published in January 1942 in Mineral Industry Surveys HSS 297 by the Bureau of Mines. These two figures differ largely because the annual canvass of the Bituminous Coal Division includes only mines with 1,000 tons or more yearly production, whereas the canvass of the Bureau of Mines is concerned with the production of all mines in which men are employed and hence are exposed to accident hazards incident to mining.

SALIENT STATISTICS

TABLE 1.—*Salient statistics of the bituminous coal and lignite industry in the United States, 1939–41*

[All tonnage figures represent net tons]

	1939	1940	1941
Production	394,855,325	460,771,500	[1] 511,290,000
Exports to Canada and Mexico [2]	9,975,919	13,537,342	(3)
Exports overseas and all other [2]	1,614,559	2,928,586	(3)
Imports [2]	355,115	371,571	(3)
Consumption in the United States (calculated) [4]	379,768,962	438,250,143	(3)
Stocks at end of year:			
Industrial consumers and retail yards	44,571,000	50,998,000	62,737,000
Stocks on upper Lake docks	7,590,254	6,998,258	7,777,446
Unbilled loads, at mines or in classification yards [5]	1,553,100	1,298,300	919,700
Price indicators (average per net ton):			
Average cost of railroad fuel purchased, f. o. b. mines [6]	$1.91	$1.88	$2.02
Average cost of coking coal at merchant byproduct ovens [7]	$4.57	$4.40	$4.67
Average cost of bunker coal to vessels in foreign trade [8]	$4.83	$4.81	(3)
Average value of exports to all countries (at port) [9]	$3.69	$3.69	(3)
Average retail price—38 cities [10]	$8.52	$8.60	$9.15
Average railroad freight charge per net ton [11]	$2.23	$2.22	$2.22
Underground loading machinery sold: [12]			
Mobile loading machines (number)	292	233	367
Scrapers (number)	18	36	8
Conveyors, including those with duckbills (units)	1,095	1,573	1,800
Pit-car loaders (units)	2	3	10
Average number of men employed at mines operating [13]	421,788	439,075	[1] 459,000
Fuel-efficiency indicators:			
Pounds of coal per kw.-hr. at electric power plants [14]	1.39	1.35	1.34
Pounds per 1,000 gross ton-miles—railroads [15]	113	112	111

[1] Subject to revision.

[1] Figures represent output and number of working days in that part of week included in calendar year shown. Total production for week of January 4, 1941, was 8,956,000 tons; for week of January 3, 1942, it was 9,844,000 tons.

[2] Average daily rate of production for entire week and not for working days in calendar year shown.

TABLE 3.—*Estimated monthly production of coal in the United States in 1941, by States, in thousands of net tons*

[Bituminous coal and lignite figures are preliminary estimates based upon railroad carloadings and river shipments of coal and beehive coke, supplemented by direct reports from a number of mining companies, local coal operators' associations, and detailed monthly production statistics compiled by the State Mine Departments of Colorado, Illinois, Pennsylvania, Washington, and West Virginia. In making the estimates, allowance is made for commercial truck shipments, local sales, and colliery fuel, and for small trucking mines producing over 1,000 tons a year. Where a mine is on the border between two States, the production is accredited to the State from which the coal is extracted, rather than the State in which the tipple is located. The estimates here given are based upon the latest information available and differ in some cases from the current figures previously published in the Weekly Coal Reports.]

1941 [9]	2,710	64,756	(10)	90,906	10,529	82,609	(10)	(10)	(10)	(10)	(10)

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 799.
[2] Department of Commerce.
[3] Geological Survey and Federal Power Commission. Represents all coal consumed by public utility power plants in power generation, including bituminous coal, anthracite, lignite, and a small amount of coke.
[4] Interstate Commerce Commission. Represents bituminous coal and lignite consumed as locomotive fuel by class I steam railways, excluding switching and terminal companies. In 1940, the consumption by class I line-haul railways plus the purchases by class II and class III railways plus all switching and terminal companies combined was 91,047,281 net tons of bituminous coal and lignite. Similar data for 1941 are not yet available. (Note: This is a revision of footnote 4, p. 768, Minerals Yearbook, Review of 1940.)
[5] Bureau of Mines.
[6] Obtained by subtracting the known items from the calculated total consumption. Includes general manufacturing, domestic, and many miscellaneous uses.
[7] Production plus imports minus exports, plus or minus changes in consumers' stocks.
[8] Includes imports.
[9] Subject to revision.
[10] Figures not available for publication.

STOCKS HELD BY CONSUMERS

TABLE 5.—*Stocks of bituminous coal and lignite in hands of commercial consumers and in retail dealers' yards in the United States, 1940–41*

Date	Total stock (net tons)	Days' supply at current rate of consumption on date of stock taking: Byproduct coke plants	Steel plants	Other industrials	Coal-gas plants	Electric utilities	Retail yards	Railroads	Cement mills	Total

[1] Unadjusted for coal in transit during suspension of mining in April 1941.

FUEL EFFICIENCY

TABLE 6.—*Indicators of effect of fuel economy on consumption of coal in the United States per unit of performance since the World War of 1914–18*

	Pounds	Reduction from base period (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average:		
1919–20	170	
1940	112	34.1
1941	111	34.7
Pounds per passenger-train car-mile:		
Average:		
1919–20	18.5	
1940	15.0	18.9
1941	14.9	19.5
Electric public utility power plants:		
Pounds per kilowatt-hour:		
1919	3.2	
1940	1.4	56.3
1941	1.3	59.4
Iron and steel—pounds coking coal per gross ton of pig: [1]		
1918	3,577	
1940	2,846	20.4
1941	2,828	20.9
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913–41, expressed as percent of coal used for all coke in 1941 [2]		18.9

[1] Includes only savings through higher yields of merchantable coke per ton of coal charged and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are covered in next item.

[2] These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and cooking, and to a small extent for automotive fuel.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER

The procedure used in making the calculations on relative rate of growth of energy is described in detail in Minerals Yearbook, Review of 1940 (p. 774).

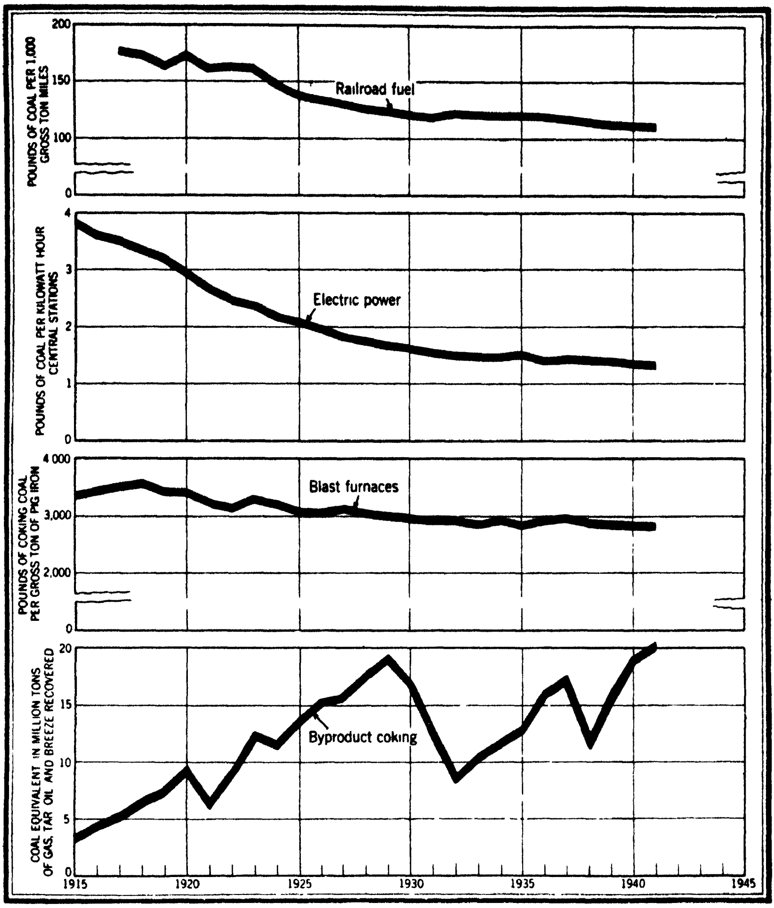

FIGURE 4.—Trends of fuel efficiency in the United States, 1915–41.

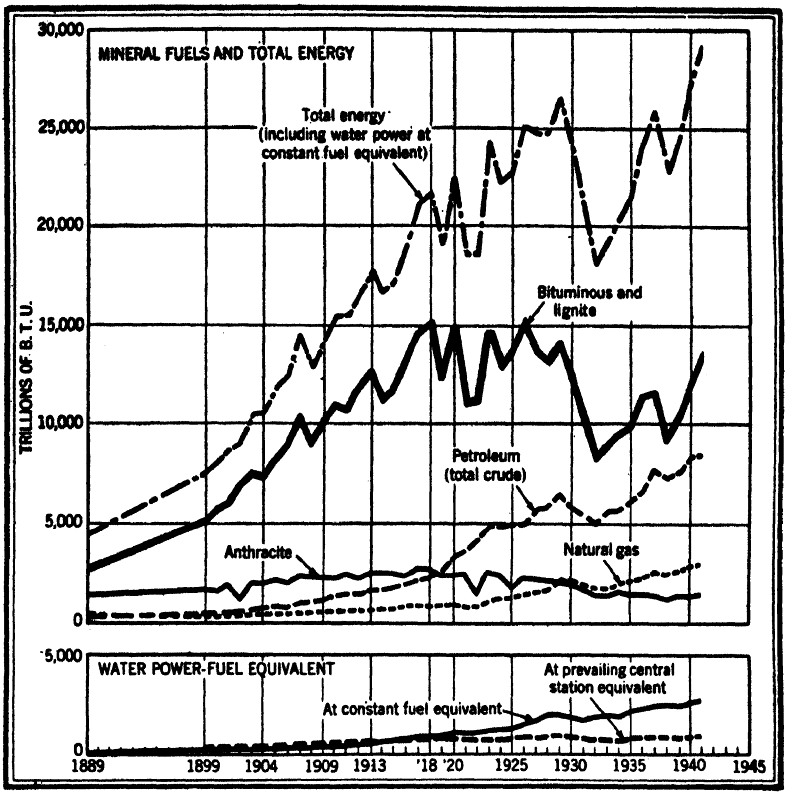

FIGURE 5.—Annual supply of energy from mineral fuels and water power in the United States, 1889-1941.

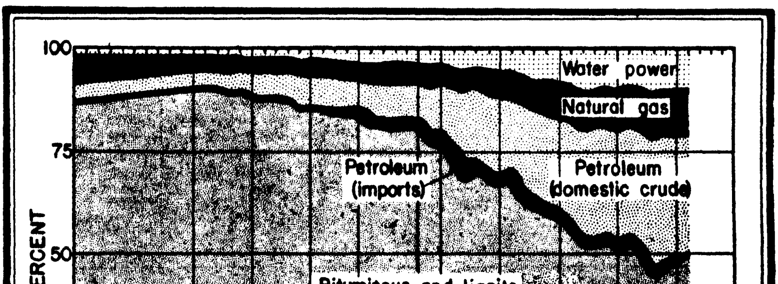

FIGURE 6.—Percentage of total B. t. u. equivalent contributed by the several sources of energy in the United States, counting water power at constant fuel equivalent, 1889-1941. If water power is counted at the prevailing fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1899 and 3.4 percent in 1941, and the proportions of the other sources of energy are affected accordingly.

TABLE 7.—*Annual supply of energy from mineral fuels and water power in the United States, 1933–41,*[1] *in trillions of B. t. u.*[2]

Year	Coal: Pennsylvania anthracite	Coal: Bituminous coal and lignite	Coal: Total	Petroleum (total crude, including that refined): Domestic production	Petroleum: Imports	Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (fuel equivalent): At constant fuel equivalent[3]	Water power: At prevailing central station equivalent[4]	Grand total energy: Water power at constant fuel equivalent	Grand total energy: Water power at prevailing central station equivalent
1933	1,348	8,741	10,089	5,434	191	1,672	7,297	17,386	1,931	711	19,317	18,097
1934	1,555	9,415	10,970	5,448	213	1,904	7,565	18,535	1,896	698	20,431	19,233
1935	1,419	9,756	11,175	5,980	193	2,060	8,233	19,408	2,207	806	21,615	20,214

1937	1,410	11,673	13,083	7,675	165	2,588	10,428	23,511	2,446	871	25,957	24,382
1938	1,255	9,132	10,387	7,286	158	2,468	9,912	20,299	2,466	866	22,765	21,165
1939	1,400	10,345	11,745	7,590	199	2,663	10,452	22,197	2,423	838	24,620	23,035
1940	1,400	12,072	13,472	8,119	256	2,860	11,235	24,707	2,620	880	27,327	25,587
1941 [5]	1,478	13,396	14,874	8,425	(6)	2,978	[6] 11,403	[6] 26,277	2,804	934	[6] 29,081	[6] 27,211

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 807.
[2] The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public utility plants since 1919. Otherwise the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufacturers and mines and of 40 percent for public utilities.
[3] Assuming 4.02 pounds per kilowatt-hour, which is average of central-electric-station practice in 1913, the base period used.
[4] Assuming the average central-station practice for each of the years for which data are available, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.34 pounds in 1941.
[5] Subject to revision.
[6] Excludes imports of petroleum. Figures not available for publication.

TABLE 8.—*Index numbers for relative rate of growth of coal, oil, and water power in the United States, 1933–41*[1]

[The figures are expressed as a percentage of the 1918 rate]

Year	Coal: Pennsylvania anthracite	Coal: Bituminous coal and lignite	Coal: Total	Petroleum (total crude): Domestic production	Petroleum: Imports	Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (at constant fuel equivalent)	Grand total: With water power at constant fuel equivalent	Grand total: With water power at prevailing central station equivalent

FINAL BITUMINOUS COAL AND LIGNITE STATISTICS FOR 1939 AND 1940

SUMMARY BY STATES

TABLE 10.—*Production, value, employment, days active, and output per man-shift at bituminous coal and lignite mines in the United States in 1939, by States*

[Exclusive of mines producing less than 1,000 tons]

State	Disposition of coal produced (net tons)						Average value per ton [4]	Average number of wage earners and working proprietors on active days (excluding shut-down periods)				Average number of full days mines were active	Tons of coal produced on active days per man-shift
	Loaded for shipment by rail or water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Used by mine employees, taken by locomotive tenders at tipple, or other uses at mines [2]	Used at mine for power and heat or made into beehive coke at mine [3]	Net changes in stocks of coal at mines Jan. 1, 1939, to Jan. 1, 1940	Total quantity		Underground	Surface		Total		
									In strip pits	All others			
Alabama	11,210,512	672,803	119,431	72,707	−28,778	12,046,675	$2.30	17,943	90	2,851	20,884	183	3.16

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mines to points of use by conveyor, chute, or aerial tramway.

[3] Includes coal made into beehive coke at mines in following States Colorado, 97,591 tons; Pennsylvania, 1,554,179 tons; Utah, 13,825 tons; Virginia, 292,152 tons; and West Virginia, 131,728 tons—grand total, 2,089,475 tons.

[4] Value of all coal produced, f. o. b. mine or cleaning plant, excluding selling cost. The value of cleaned coal, rather than that of raw coal, was used in cases of operations that cleaned coal.

[5] Not shown separately to avoid disclosure of individual operations.

[6] Estimate made from various sources on disposition of lignite has been included for comparative purposes; lignite schedule did not ask for this break-down.

TABLE 11.—*Production, value, employment, days active, man-days, and output per man per day at bituminous coal and lignite mines in the United States in 1940, by States*

[Exclusive of mines producing less than 1,000 tons]

State	Disposition of coal produced (net tons)					Average value per ton [4]	Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
	Loaded for shipment by rail or water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Used by mine employees, taken by locomotive tenders at tipple, or other uses at mine [2]	Used at mine for power and heat or made into beehive coke at mine [3]	Total quantity		Underground	Surface		Total

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mines to points of use by conveyor, chute, or aerial tramway.

[3] Includes coal made into beehive coke at mines in following States: Colorado, 95,735 tons; Kentucky, 1,273 tons; Pennsylvania, 3,239,464 tons; Tennessee, 8,818 tons; Utah, 14,537 tons; Virginia, 330,818 tons; and West Virginia, 354,405 tons—grand total, 4,045,050 tons.

[4] Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[5] Figures on lignite compiled by Bureau of Mines; see lignite tables, 1940, at end of this chapter. As lignite schedule did not require exactly same break-down on disposition of coal produced as shown in this table, an estimate has been made where feasible for items "shipped by truck or wagon" and "used by mine employees, taken by locomotive tenders at tipple, or other uses at mine." Sum of these items equals sum of items "commercial sales by truck or wagon" and "other sales to local trade, or used by employees, or taken by locomotives at tipple," as published by Bureau of Mines.

[6] Lignite figures exclude selling cost.

PRODUCTION BY WEEKS AND MONTHS

TABLE 12.—*Bituminous coal and lignite produced in the United States in 1939, with estimates by weeks*

Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)	Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)
Jan. 7	7,815,000	5.1	1,532,000	July 15	7,080,000	6	1,180,000

13	8,381,000	6	1,397,000				

[1] Figures represent output and number of working days in that part of week included in calendar year shown. Total production for week of January 4, 1941, was 8,956,000 tons.

[2] Average daily production for entire week and not for working days in calendar year shown.

TABLE 14.—*Coal produced in the United States in 1939, by States, with estimates by months, in thousands of net tons*

[Totals for year based upon final complete returns to Bituminous Coal Division from all operators known to have produced more than 1,000 tons in year. Apportionment of known yearly total among 12 months based upon best information available—in some States upon direct tonnage reports by operators to State mine department but in most cases upon current records of railway carloadings and waterway shipments]

[1] In Alaska, 1 mine that should be included in Class 2 and 1 mine that should be included in Class 5 are included in Class 3 to avoid disclosure of individual operations.

AVERAGE VALUE

TABLE 18.—*Trend of average value in the United States of bituminous coal and lignite, per net ton, f. o. b. mines, 1929–40* [1]

Year	Bituminous coal [2] (subject to regulation under 1937 Act)	Lignite [3]	Total
Average value per ton, less selling cost (Bureau of Mines series):			
1929	$1.782	$1.548	$1.781
1930	1.702	1.556	1.701
1931	1.542	1.410	1.541
1932	1 313	1.313	1.313
1933	1.337	1.188	1.336
1934	1.751	1.387	1.749
1935	1.772	1.120	1.767
1936	1.761	1.061	1.756
Average gross realization, including selling cost (Bituminous Coal Division series):			
1936	1.831	[4] 1.061	1.826
1937	1.946	[4] 1.080	1.939
1938	1.955	[4] 1.071	1.947
1939 [5]	1.850	1.158	1.845
1940	1.913	[4] 1.156	1.908

[1] For explanation see Minerals Yearbook, Review of 1940, pp. 778–779
[2] Includes all coal produced other than Pennsylvania anthracite and the lignite included in the second column.
[3] North Dakota, South Dakota, and the lignite counties of Montana and Texas.
[4] Figures of Bureau of Mines, excluding selling cost as before. Data on sales realization were not collected from lignite mines by the Bituminous Coal Division.
[5] Producers were asked to exclude selling cost in reporting value, but a number of them included such costs.

LABOR STATISTICS

TABLE 19.—*Number of bituminous coal and lignite mines in the United States in 1940, having established working shift of certain length, and number of men employed therein*

State	7 hours		8 hours		9 hours		All others [1]		Total

Total waterway shipments		22,229,364	22,229,364	29,493,058	29,493,058
Total loaded at mines for shipment by railroads and waterways		353,418,984	353,418,984	409,880,732	409,880,732
Shipped by truck or wagon		29,533,824	29,533,824	35,540,476	35,540,476
Used by mine employees and owners for house coal.		1,901,408	1,901,408	2,035,201	2,035,201
Taken by locomotive tenders at tipple.		826,556	826,556	939,058	939,058
Used at mine for power and heat		2,565,276	2,565,276	2,442,989	2,442,989
Made into beehive coke at mine		2,089,475	2,089,475	4,045,050	4,045,050
Transported from mines to points of use by conveyor, chute, or aerial tramway.		4,317,465	4,317,465	5,887,994	5,887,994
Total production		[5] 394,855,325	[5] 394,855,325	460,771,500	460,771,500

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water. In general, the figures show the quantity of bituminous coal and lignite originated for each railroad and waterway as reported by the mine operators. It must be noted that in 1 year an operator may report coal loaded on a subsidiary railroad and in another year the same operator may report coal loaded on the parent railroad system.

[2] Reported as Mobile & Ohio for 1939.

[3] Texas lignite mines shipping over Missouri-Kansas-Texas, Rockdale, Sandow & Southern, St. Louis Southwestern of Texas, and Texas Short Line have been included with International-Great Northern.

[4] Reported as Gulf, Mobile & Ohio for 1940.

[5] Includes 202,337 tons of coal reported as net changes in stocks at mines, January 1, 1939, to January 1, 1940.

METHODS OF RECOVERY

[2] Small quantity of lignite "cut by machines" in Montana excluded.
[3] Montana lignite included with North Dakota lignite

STRIPPING OPERATIONS

TABLE 25.—*Stripping operations of all types in the bituminous coal and lignite fields of the United States in 1939, by States and counties*

Returns for mines that recover coal both by stripping and by underground operations do not permit separating number of men engaged in stripping from those engaged in other work. For this reason, figures for men employed represent all persons working at such mines, including those underground. Total tons produced by both methods at these same mines are also shown]

State and county	Number of strip pits	Number of power shovels[1]			Coal produced (net tons)		Average number of wage earners and working proprietors on active days (excluding shut-down periods)				Average number of full days mines were active	Number of man-shifts worked by wage earners and working proprietors on active days (excluding shut-down periods)	Tons of coal produced on active days per man-shift

Grand total	537	206	184	524	37,722,583	[5] 13,873	[5] 197	[5] 13.97

[1] Number of power shovels shown represents equipment in use or available for use as of Jan. 1, 1940.

[2] Excludes coal produced by underground mining conducted in same operation.

[3] Colorado, Montana (bituminous), South Dakota (lignite), Tennessee, and Texas (lignite).

[4] Includes operations in Arkansas, Kentucky, North Dakota (lignite), Ohio, Pennsylvania, Tennessee, Washington, and Wyoming, in which output was obtained by both methods. In addition to the 589,905 tons produced by stripping, this group of 23 mines obtained 534,948 tons by underground methods—their total production by both methods being 1,124,853 tons.

[5] Includes data on underground mining conducted in same operation.

TABLE 28.—*Summary of operations of power strip pits proper in the bituminous coal and lignite fields of the United States in 1940, by States*

State	Number of strip pits	Number of power shovels: Steam	Electric	All others	Net tons mined by stripping [1]	Number of men employed	Average number of days mines were active	Average tons per man per day

[1] Included under "Undistributed."
[2] Alaska, Missouri, and New Mexico.

MECHANICAL LOADING

The quantity of coal loaded mechanically at underground mines in the United States continued to advance sharply in 1939 and 1940. There were 85,092,836, 110,711,970, and 147,870,252 net tons mechanically loaded at bituminous coal and lignite mines during 1938, 1939, and 1940, respectively, and 10,151,669, 11,773,833, and 12,326,000 net tons mechanically loaded at Pennsylvania anthracite mines. The percentage of total underground bituminous coal and lignite production that was mechanically loaded increased from 27 in 1938 to 31 in 1939 and 35 in 1940. Detailed statistics on mechanical loading are given in the following tables (30–37). Data in these tables pertain to underground mines and do not include strip mines or equipment used for handling coal on the surface.

TABLE 30.—*Units of mechanized loading equipment sold to bituminous coal, lignite, and Pennsylvania anthracite mines in the United States, 1934–41, as reported by manufacturers* [1]

Type of equipment	1934	1935	1936	1937	1938	1939	1940	1941	Percent of increase or decrease, 1941 from 1940
Mobile loaders	55	115	344	292	241	292	233	368	+57.9
Scrapers [2]	34	22	28	29	10	26	39	11	−71.8
Conveyors [3]	610	681	994	1,095	990	1,311	1,762	2,130	+20.9
Pit-car loaders	26	28	11	32	139	2	3	10	+233.3

[1] Data for 1934–37 include reports from 28 manufacturers; data for 1938, 1939, 1940, and 1941 include reports from 29, 31, 32, and 32 manufacturers, respectively.
[2] Reported as scrapers or scraper haulers and hoists.
[3] Includes hand-loaded conveyors and those equipped with duckbills and other self-loading heads. As sales of both loading heads and shaker conveyors are counted, figures involve a certain measure of overlap that cannot be determined accurately. It should also be noted that a small number of conveyors were for use in conjunction with mobile loading machines.

TABLE 31.—*Sales of mechanized loading equipment in the United States in 1941, compared with total number of machines in active use in preceding years*

Type of equipment	Number of machines in active use, as reported by mine operators [1]									1941 Number of machines sold, as reported by manufacturers
	1931	1932	1933	1934	1935	1936	1938	1939	1940	
Bituminous coal and lignite mines:										
Mobile loading machines	583	548	523	534	657	980	1,405	1,573	1,720	367
Scrapers	146	128	93	119	78	106	117	131	116	8
Pit-car loaders	3,428	3,112	2,453	2,288	2,098	1,851	1,392	873	697	10
Conveyors equipped with duckbills and other self-loading heads	165	159	132	157	179	234	346	559	656	(2)
Hand-loaded conveyors—number of units	(3)	(3)	525	574	670	936	1,526	1,834	2,263	[4] 1,800
Anthracite mines (Pennsylvania):										
Mobile loading machines	5	11	18	14	1	(5)	(6)	(6)	(5)	1
Scrapers	457	479	455	517	507	[7] 504	545	535	[7] 547	3
Pit-car loaders	28	24	19	25	22	(6)	(6)	(6)	(6)	----------
Conveyors equipped with duckbills and other self-loading heads	1	17	12	13	30	(6)	(6)	(6)	(6)	(2)
Hand-loaded conveyors—number of units	547	818	940	1,338	1,563	[8] 1,790	[9] 1,831	[9] 1,997	[8] 2,189	[4] 330

[1] Data for bituminous coal and lignite mines for 1937 not available. Minerals Yearbook, 1939, p. 857, shows for 1937 in the anthracite mines 539 scrapers and 1,855 conveyors and pit-car loaders including a few mobile loaders.
[2] Included with hand-loaded conveyors.
[3] Number of units not reported.
[4] Reported as face conveyors (hand-loaded), "shaker drives," and "duckbills." Figures for number sold not exactly comparable with number in use in 1940, because of uncertainties in defining what constitutes a conveyor and because of certain overlaps in reporting duckbill loading heads and shaker conveyors.
[5] Included with scrapers.
[6] Included with hand-loaded conveyors.
[7] Includes mobile loading machines.
[8] Includes pit-car loaders and conveyors equipped with duckbills or self-loading heads.
[9] Includes mobile loaders, pit-car loaders, and conveyors equipped with duckbills or self-loading heads.

TABLE 32.—*Comparison of mobile loaders, scrapers, and conveyors in actual use in coal mines in the United States, 1939–40, and sales reported in 1941, by States and regions*

State and region	Mobile loaders: In use in— 1939	Mobile loaders: In use in— 1940	Mobile loaders: Sales in 1941	Scrapers: In use in— 1939	Scrapers: In use in— 1940	Scrapers: Sales in 1941	Conveyors [1]: In use in— 1939	Conveyors [1]: In use in— 1940	Conveyors [1]: Sales in 1941

MECHANICAL CLEANING

Bituminous coal mechanically cleaned increased from 63,454,588 net tons in 1938 to 79,376,672 tons in 1939 and 102,205,186 tons in 1940. During the 3 years, this represents annual increases in mechanical cleaning of 18, 20, and 22 percent, respectively, of the total bituminous coal and lignite output. No mechanical cleaning plants have been installed at lignite mines. Detailed data on mechanical cleaning are shown in the following tables (38–44).

Consumer-operated cleaning plants include plants owned by steel companies which receive coal from various mines (but usually from affiliated coal companies), clean it, and then consume it directly at the plant.

TABLE 38.—*Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States, 1939–40, in net tons of clean coal* [1]

Method of cleaning	1939 (net tons)	1940 (net tons)	Increase, 1940 over 1939	
			Net tons	Percent
By wet methods:				
At mines	60,881,144	78,475,302	17,594,158	28.9
At central washeries operated by consumers	6,800,587	8,750,220	1,949,633	28.7
Total wet methods	67,681,731	87,225,522	19,543,791	28.9
By pneumatic methods	11,694,941	14,979,664	3,284,723	28.1
Grand total	79,376,672	102,205,186	22,828,514	28.8

[1] Figures do not include Alaska, which had 1 wet-washing installation.

TABLE 39.—*Bituminous coal cleaned in the United States, 1939–40, by types of equipment in actual operation* [1]

[Coal cleaned and plants operated by consumers at central washeries in Colorado and Pennsylvani included]

Type of equipment	Plants in operation		Net tons of clean coal		Increase or decrease, 1940 from 1939		Percent cleaned by each type

Washington	1,549,408	1,366,754	182,654	11.8	1,548,729
West Virginia [7]	20,766,527	18,812,410	1,954,117	9.4	42,445,104
Other States [8]	17,161,041	16,058,171	1,102,870		26,787,491
Total at mines only [9]	81,675,853	72,576,085	9,099,768	11.1	133,260,996
Consumer plants [10]	7,140,590	6,800,587	340,003	4.8	
Grand total	88,816,443	79,376,672	9,439,771	10.6	

[1] Excludes Alaska.
[2] Exact figures on raw coal or refuse could not be furnished by many operators, in such instances, estimates were made from all available information at hand.
[3] In Alabama (for example) for every 100 tons of raw coal cleaned in 1939, an average of 12.2 tons of refuse was discarded and 87.8 tons of clean marketable coal was obtained.
[4] Based upon shipping weights, includes some marketable coal that did not pass through cleaning plants.
[5] Included under "Other States."
[6] Includes some coal mined in Pennsylvania and cleaned in Ohio.
[7] Includes some coal mined in West Virginia and cleaned in Ohio.
[8] Includes Arkansas, Colorado, Maryland, Michigan, Montana, New Mexico, Pennsylvania, Texas, and Utah.
[9] Includes all mechanical cleaning other than washeries operated by consumer steel companies.
[10] Includes central washeries in Colorado and Pennsylvania operated by consumer steel companies.

TABLE 44.—*Result of operations at bituminous coal cleaning plants in the United States in 1940, by States, in net tons* [1]

State	Total raw coal moved to cleaning plants [2]	Coal obtained in cleaning process	Refuse resulting in cleaning process [2]	Percent of refuse to raw coal [3]	Total production from mines that moved coal to cleaning plants [4]
Alabama	14,758,435	12,923,860	1,834,575	12.4	14,030,911
Colorado	(5)	(5)	(5)	9.0	(5)
Illinois	22,428,658	18,840,805	3,587,853	16.0	31,803,487

Washington	1,599,221	1,362,856	236,365	14.8	1,491,793
West Virginia [7]	26,073,317	23,384,440	2,688,877	10.3	52,002,066
Other States [8]	22,743,963	20,814,184	1,929,779		31,846,532
Total at mines only [9]	106,407,378	93,454,966	12,952,412	12.2	161,671,567
Consumer plants [10]	9,193,244	8,750,220	443,024	4.8	
Grand total	115,600,622	102,205,186	13,395,436	11.6	

[1] Excludes Alaska.
[2] Exact figures on raw coal or refuse could not be furnished by many operators; in such instances, estimates were made from all available information at hand.
[3] In Alabama (for example) for every 100 tons of raw coal cleaned in 1940, an average of 12.4 tons of refuse was discarded and 87.6 tons of clean coal was obtained.
[4] Based upon shipping weights, includes some marketable coal that did not pass through cleaning plants.
[5] Included under "Other States."
[6] Includes some coal mined in Pennsylvania and cleaned in Ohio.
[7] Includes some coal mined in West Virginia and cleaned in Ohio.
[8] Includes Arkansas, Colorado, Georgia, Michigan, Montana, New Mexico, Pennsylvania, and Utah.
[9] Includes all mechanical cleaning other than washeries operated by consumer steel companies.
[10] Includes central washeries in Colorado and Pennsylvania operated by consumer steel companies.

DETAILED STATISTICS BY STATES AND COUNTIES

TABLE 45.—*Production, value, employment, days active, and output per man-shift at bituminous coal and lignite mines in the United States in 1939, by States and counties*

[Exclusive of mines producing less than 1,000 tons]

ALABAMA

County	Disposition of coal produced (net tons): Loaded for shipment by rail or water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Used by mine employees, taken by locomotive tenders at tipple, or other uses at mines [2]	Used at mine for power and heat or made into beehive coke at mine	Net changes in stocks of coal at mines Jan. 1, 1939, to Jan. 1, 1940	Total quantity	Average value per ton [3]	Average number of wage earners and working proprietors on active days (excluding shut-down periods): Underground	Surface: In strip pits	Surface: All others	Total	Average number of full days mines were active	Tons of coal produced on active days per man-shift

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mines to points of use by conveyor, chute, or aerial tramway.

[3] Value of all coal produced, f. o. b. mine or cleaning plant, excluding selling cost. The value of cleaned coal, rather than that of raw coal, was used in cases of operations that cleaned coal.

[4] No coal was made into beehive coke at mines in 1939.

[5] Includes 97,591 tons made into beehive coke at mines in Las Animas County, Colo., in 1939.

[6] Not shown separately to avoid disclosure of individual operations.

[7] "Other counties" in Illinois include Adams, Bond, Bureau, Christian, Clinton, Crawford, Edgar, Greene, Hancock, Henry, Jackson, Jefferson, Logan, Marion, Mason, Morgan, Scott, Warren, Washington, White, Will, and Woodford.

[8] Much of the output of the State obtained from strip pits or by use of loading machines, in which types of operations production per man-shift is large.

[9] Production of Home Riverside and Alston mines is credited to Missouri rather than to Kansas.

[10] "Other counties" in Eastern Kentucky include Breathitt, Carter, Elliott, Johnson, Lawrence, McCreary, Magoffin, Martin, Morgan, Owsley, Pulaski, and Wolfe.

[11] Output obtained chiefly from strip pits in which production per man-shift is large.

[12] Other counties in Missouri include Barton, Bates, Callaway, Chariton, Clark, Dale, Daviess, Grundy, Howard, Jasper, Johnson, Lincoln, Macon, Monroe. Morgan, Platte, Ralls, and Warren.

[13] "Other counties" in Montana (bituminous coal) include Blaine, Carbon, Cascade, Fergus, Flathead, Gallatin, Judith Basin, Park, Phillips, Pondera, and Rosebud.

[14] Estimate made from various sources on disposition of lignite has been included for comparative purposes; the lignite schedule did not ask for this break-down. Data by counties not available.

[15] Includes coal made into beehive coke at mines in following counties in Pennsylvania in 1939: Cambria, 45,545 tons; Fayette, 997,104 tons; Indiana, 131,001 tons; and Westmoreland, 380,529 tons—State total, 1,554,179 tons.

[16] Includes 13,825 tons made into beehive coke at mines in Carbon County, Utah, in 1939.

[17] Includes 292,152 tons made into beehive coke at mines in Wise County, Va., in 1939.

[18] Includes coal made into beehive coke at mines in following counties in West Virginia in 1939: Fayette, 119,495 tons; Logan, 154 tons: and Preston, 12,079 tons—State total, 131,728 tons.

[19] "Other counties" in Wyoming include Campbell, Carbon, Crook, Fremont, Johnson, Lincoln, Natrona, Sheridan, Sweetwater, and Uinta.

TABLE 46.—*Production, value, employment, days active, man-days, and output per man per day at bituminous coal and lignite mines in the United States in 1940, by States and counties*

[Exclusive of mines producing less than 1,000 tons]

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mines to points of use by conveyor, chute, or aerial tramway.

[3] Value received or charged for coal, f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[4] No coal was made into beehive coke at mines in 1940.

[5] Includes 95,735 tons made into beehive coke at mines in Las Animas County, Colo., in 1940.

[6] "Other counties" in Illinois include Adams, Bond, Crawford, Hancock, Jefferson, Logan, McDonough, Macon, Marion, Marshall, Montgomery, Scott, Warren, White, Will, and Woodford.

[7] Much of output is obtained from strip pits or by use of loading machines, in which types of operations production per man per day is large.

[8] Production of Home Riverside and Alston mines is credited to Missouri; production of Hume-Sinclair (Tiger mine) is credited to Kansas.

[9] Output obtained chiefly from strip pits in which production per man per day is large.

[10] Includes 1,273 tons made into beehive coke at mines in Jackson County, Ky., in 1940.

[11] "Other counties" in Eastern Kentucky include Elliott, Greenup, Lawrence, Leslie, Magoffin, Martin, Morgan, and Owsley.

[12] "Other counties" in Missouri include Audrain, Chariton, Clark, Dade, Daviess, Grundy, Howard, Jasper, Johnson, Lincoln, Miller, Monroe, Morgan, and Saline.

[13] "Other counties" in Montana bituminous coal include Blaine, Fergus, Flathead, Judith Basin, Park, Phillips, Pondera, and Powder River.

[14] Figures on lignite compiled by Bureau of Mines, see lignite tables, 1940, at end of this chapter. As lignite schedule did not require exactly same break-down on disposition of coal produced as shown in this table, an estimate has been made where feasible for items "shipped by truck or wagon," "used by mine employees," "taken by locomotive tenders at tipple," and "transported from mines to points of use by conveyor, chute, or aerial tramway." Sum of these items equals sum of items "commercial sales by truck or wagon" and "other sales to local trade, or used by employees, or taken by locomotives at tipple," as published by Bureau of Mines. For more detailed information on lignite by counties, see section on lignite at end of chapter.

[15] Excludes selling cost.

[16] Includes coal made into beehive coke at mines in following counties in Pennsylvania in 1940. Bedford, 989 tons, Cambria, 45,882 tons; Fayette, 2,199,593 tons; Greene, 3,098 tons; Indiana, 233,673 tons; and Westmoreland, 756,229 tons—State total, 3,239,464 tons.

[17] Includes 8,818 tons made into beehive coke at mines in Grundy County, Tenn., in 1940.

[18] Includes 14,537 tons made into beehive coke at mines in Carbon County, Utah, in 1940.

[19] Includes coal made into beehive coke at mines in following counties in Virginia in 1940. Lee, 800 tons: Wise, 330,018 tons; State total, 330,818 tons.

[20] Includes coal made into beehive coke at mines in following counties in West Virginia in 1940: Fayette, 306,487 tons; Preston, 47,918 tons; State total, 354,405 tons.

STATISTICS ON LIGNITE IN 1940[3]

PRODUCTION

The Bureau of Mines prepares final statistics of the lignite industry from an annual canvass, by mail, of operators of lignite properties included in the areas mapped as "lignite" in Geological Survey Professional Paper 100–A, The Coal Fields of the United States. Subbituminous coal is not included. The data on individual operations furnished by the producers are voluntary and confidential, as is customary in the statistical surveys of the Bureau of Mines.

Lignite production in 1940 totaled 2,939,201 net tons, a small decrease from the 3,042,537 tons produced in 1939. These figures are exclusive of many of the small mines producing less than 1,000 tons. The average value per ton was $1.16 in 1940 compared with $1.13 in 1939. The average value per ton by States ranged from a low of $1.05 for Texas to a high of $1.78 for Montana. The number of men employed in 1940 totaled 2,070 compared with 2,096 in 1939, and the average output per man per day for the same periods was 7.99 and 7.61 tons, respectively. The average number of days worked by the industry was 178 in 1940 compared with 191 in 1939. A much larger percentage of the total output of lignite results from stripping operations than in either anthracite or bituminous-coal mining. Of the total lignite output 48 percent (1,447,449 tons) was produced in strip pits in 1939 whereas 51 percent (1,512,308 tons) of the total in 1940 resulted from strip-pit operations. No labor disturbances were reported.

In 1940, as for many years in the past, North Dakota was the largest producer of lignite, followed in order by Texas, South Dakota, and Montana. The North Dakota output represented 75 percent of the United States total, that of Texas 21 percent, and South Dakota and Montana together 4 percent.

Reports of the Federal Power Commission show that 1,538,174 tons of lignite were consumed in 1939 for generating electric energy in the United States. In 1940, 1,452,412 tons were so used, and this tonnage was equivalent to 49 percent of the total production. Consumption in the West North Central Division was 547,366 tons, in the West South Central and Mountain Divisions 516,531 and 386,991 tons, respectively, and in the East South Central Division, 1,524 tons.

The following tables include detailed statistics on the lignite industry in 1940. Similar data for 1941 were not available in time to be included in this chapter, but they will be published later in mimeographed form and may be obtained upon request to the Coal Economics Division of the Bureau of Mines.

[3] Compiled by J. A. Corgan and A. V. Coleman, Coal Economics Division, Bureau of Mines.

TABLE 47.—*Summary of production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1940, by States*

	North Dakota	Texas	South Dakota	Montana [1]	Total
Production (net tons):					
Loaded at mines for shipment	1,566,976	592,720	37,285	5,472	2,202,453
Commercial sales by truck or wagon	447,694	6,784	28,521	41,666	524,665
Other sales to local trade, or used by employees, or taken by locomotives at tipple	[2] 177,371	3,650	[2] 279	1,030	[2] 182,330
Used at mines for power and heat	26,393	3,264	([3])	96	[3] 29,753
Total production: 1940	2,218,434	606,418	66,085	48,264	2,939,201
1939	2,131,252	814,022	49,495	47,768	3,042,537
Value:					
Total: 1940	$2,587,000	$637,000	$88,000	$86,000	$3,398,000
1939	$2,425,000	$875,000	$69,000	$83,000	$3,452,000
Average per net ton: 1940	$1.17	$1.05	$1.33	$1.78	$1.16
1939	$1.14	$1.07	$1.39	$1.74	$1.13
Number of employees:					
Underground	654	476	12	60	1,202
Surface (including strip pits)	723	70	51	24	868
Total employees: 1940	1,377	546	63	84	2,070
1939	1,391	559	53	93	2,096
Average number of days mines operated:					
1940	182	170	168	161	178
1939	179	231	160	146	191
Man-days of labor: 1940 [4]	251,216	92,615	10,577	13,499	367,907
1939	248,755	129,120	8,502	13,565	399,942
Average output per man per day (net tons):					
1940	8.83	6.55	6.25	3.58	7.99
1939	8.57	6.30	5.82	3.52	7.61

[1] Includes output of Custer, Dawson, McCone, Richland, Roosevelt, Sheridan, and Valley Counties.
[2] Includes some lignite "made into briquets."
[3] Small amount of colliery fuel included in "Other sales to local trade."
[4] Based upon (1) "reported" number of man-shifts where operator keeps a record thereof; otherwise upon (2) "calculated" number of man-shifts, obtained by multiplying average number of men employed underground and on surface at each mine by number of days worked by mine and tipple, respectively. Using throughout "calculated" man-shifts as developed before the year 1932—namely, product of total number of men employed at each mine times tipple days—the average output per man per day was 8.59 in 1940.

TABLE 48.—*Production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1940, by States and counties*

MONTANA

County	Total production (net tons)	Value		Total number of employees	Man-days of labor [1]	Average number of days mine operated	Average net tons per man per day [1]
		Total (thousand dollars)	Average per net ton				
Custer, Dawson, and Valley	8,579	14	$1.63	14	1,886	135	4.55
McCone	4,358	8	1.84	10	1,484	148	2.94
Richland and Roosevelt	19,362	39	2.01	36	5,689	158	3.40
Sheridan	15,965	25	1.57	24	4,440	185	3.60
Total Montana: 1940	48,264	86	1.78	84	13,499	161	3.58
1939	47,768	83	1.74	93	13,565	146	3.52

See footnotes at end of table.

TABLE 48.—*Production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1940, by States and counties*—Continued

NORTH DAKOTA

County	Total production (net tons)	Value: Total (thousand dollars)	Value: Average per net ton	Total number of employees	Man-days of labor [1]	Average number of days mine operated	Average net tons per man per day [1]
Adams	48,434	61	$1.26	80	11,977	150	4.04
Billings, Bowman, Dunn, and Slope	12,163	19	1.56	19	3,020	159	4.03
Burke	260,480	305	1.17	84	17,468	208	[2] 14.91

Williams	37,624	50	1.33	58	8,877	153	4.24
Total North Dakota: 1940	2,218,434	2,587	1.17	1,377	251,216	182	8.83
1939	2,131,252	2,425	1.14	1,391	248,755	179	8.57

SOUTH DAKOTA

County	Total production (net tons)	Value: Total (thousand dollars)	Value: Average per net ton	Total number of employees	Man-days of labor [1]	Average number of days mine operated	Average net tons per man per day [1]
Corson and Dewey	61,077	80	$1.31	44	8,813	200	6.93
Harding and Meade	1,809	4	2.21	10	770	77	2.35
Perkins	3,199	4	1.25	9	994	110	3.22
Total South Dakota: 1940	66,085	88	1.33	63	10,577	168	6.25
1939	49,495	69	1.39	53	8,502	160	5.82

TEXAS

County	Total production (net tons)	Value: Total (thousand dollars)	Value: Average per net ton	Total number of employees	Man-days of labor [1]	Average number of days mine operated	Average net tons per man per day [1]
Bastrop and Milam	73,947	48	$0.65	113	11,195	99	6.61
Henderson, Titus, and Wood	532,471	589	1.11	433	81,420	188	6.54
Total Texas: 1940	606,418	637	1.05	546	92,615	170	6.55
1939	814,022	875	1.07	559	129,120	231	6.30

[1] Based upon (1) "reported" number of man-shifts where operator keeps a record thereof, otherwise upon (2) "calculated" number of man-shifts obtained by multiplying average number of men employed underground and on surface at each mine by number of days worked by mine and tipple, respectively. Using throughout "calculated" man-shifts as developed before the year 1932—namely, product of total number of men employed at each mine times tipple days—the average output per man per day in 1940 was 3.58 in Montana, 9.88 in North Dakota, 5.48 in South Dakota, and 6.56 in Texas.

[2] Output obtained chiefly from strip pits, in which production per man per day is large.

NUMBER AND SIZE OF MINES

Reports were received from 208 lignite mines in 1940. This is exclusive of many small mines producing less than 1,000 tons a year and is comparable with 206 mines reporting in 1939. North Dakota, producing about 75 percent of the total lignite output, reported 164 mines; Montana was next in order with 22 mines; South Dakota and Texas followed with 14 and 8, respectively. Five mines produced from 200,000 to more than 500,000 tons each, and the output of these mines amounted to 57 percent of the total production; 2 reported production of 100,000 to 200,000 tons each and accounted for 11 percent of the total; 3 mines reported an output of 50,000 to 100,000

tons each and accounted for 8 percent of the total; 15 mines in the 10,000- to 50,000-ton class reported 10 percent of the total; and 183 mines producing less than 10,000 tons each accounted for 14 percent of the total.

METHODS OF RECOVERY

TABLE 49.—*Lignite mined by different methods in the United States in 1940, by States, in net tons*

State	Mined by hand	Shot off the solid	Cut by machines [1]	From strip pits	Not specified	Total
Montana	[2] 53,622	[2] 538,396	12,964	[2] 44,916	4,784	48,264
North Dakota	111,044	119,274	557,408	1,405,590	25,118	2,218,434
South Dakota	2,465			61,802	1,818	66,085
Texas	(2)	(2)		(2)		606,418
Total	167,131	657,670	570,372	1,512,308	31,720	2,939,201

[1] A total of 20 machines was used—13 "permissible" and 7 of other types.
[2] Texas included with Montana.

STRIPPING OPERATIONS

Lignite recovered by stripping operations in 1940 totaled 1,512,308 tons—51 percent of the output of the industry. In 1940 the total production of lignite in North Dakota was 2,218,434 net tons; of this amount, 1,405,590 tons (63 percent) came from strip-pit operations. The output from strip pits in Texas, Montana, and South Dakota was only 106,718 tons. The number of men employed in stripping operations was 588, with an average output per man per day of 12.87 tons; 200 days was the average worked.

Table 50 gives detailed statistics for stripping operations in the lignite industry in 1940.

TABLE 50.—*Summary of stripping operations that produced lignite in the United States in 1940, by States*

State	Number of strip pits [1]	Number of shovels, dragline excavators, and coal-loading machines [2]	Coal mined by stripping (net tons)	Total value at mines (thousand dollars)	Average value per net ton	Number of employees: In strip pits	Number of employees: All others	Number of employees: Total	Average number of days mines operated	Man-days of labor [3]	Average net tons per man per day [3]
Montana and Texas	5	2	44,916	26	$0.58	24	1	25	104	2,599	17.28
North Dakota	52	35	1,405,590	1,605	1.14	371	144	515	206	105,868	13.28
South Dakota	8	2	61,802	81	1.31	39	9	48	188	9,023	6.85
Total	65	39	1,512,308	1,712	1.13	434	154	588	200	117,490	12.87

[1] Includes some pits in which stripping is done by hand.
[2] In some cases, same equipment was used for stripping or excavating and for loading coal, such duplication has been eliminated. In some cases, coal was excavated by machine and loaded by hand.
[3] Based upon (1) "reported" number of man-shifts where operator keeps an accurate record thereof, otherwise upon (2) "calculated" number of man-shifts, obtained by multiplying number of men employed at tipple, in loading coal, etc., and in stripping overburden by number of days worked in each department in so far as separately reported by operator.

WORLD PRODUCTION

[7] January to September, inclusive.

PENNSYLVANIA ANTHRACITE

By J. A. Corgan, Robert H. Ridgway, and A. V. Coleman

SUMMARY OUTLINE

REVIEW OF 1941

The production of Pennsylvania anthracite in 1941 was 56,368,267 net tons—a substantial increase from the 51,484,640 tons produced in 1940, due in part to increased consumer purchasing power, high industrial activity under pressure of war, substitution of anthracite for coke in some sections of the market, and inclusion in the 1941 figures of some illicit coal heretofore not considered in the Bureau's statistics. Compared with the First World War, the 1941 output was only a little more than half the 99,611,811 tons produced in 1917. The notable decrease in production during the period between the two wars has been due mostly to the inroads made by oil, coke, and bituminous coal in the principal anthracite markets and the loss of a large part of the market west of Buffalo, N. Y. The production figures include fresh-mined coal from underground and strip-pit operations, culm-bank output, and river coal recovered from the streams draining the Pennsylvania anthracite fields.

Much of the industry continued to operate under the voluntary production-control program inaugurated in January 1940 by the Commonwealth of Pennsylvania, the United Mine Workers of America, and producers representing more than 90 percent of the total anthracite production. By act of the General Assembly of the

Commonwealth of Pennsylvania, the State Secretary of Commerce took over administration of the program, effective November 10, 1941. It is believed that the program has benefited the anthracite industry and doubtless has brought production in closer alinement with current demand. Operation of the plan has helped also to partially solve the "bootleg" or illicit-coal problem, which has created undesirable social and industrial conditions in Pennsylvania for several years.

A joint resolution passed by the United States Senate and House of Representatives and approved by the President in December 1941 created a body known as the Federal Anthracite Coal Commission to investigate ways and means for improving economic conditions in the anthracite-producing regions of the United States. The Commission met several times in the Pennsylvania anthracite regions early in 1942, and representatives of the anthracite industry and others interested in the welfare of the anthracite regions presented a picture of the social and economic conditions resulting from the decline in anthracite production. Facts pertaining to these conditions were gathered and in April 1942 were submitted in a report to the President and the Congress.

Freight rates for anthracite were not changed greatly during 1941. Minor adjustments and equalizations were made. The so-called motor-compelled rates—inaugurated originally to compete with the trucking of anthracite—were to expire December 20, 1941, but were extended for 6 months.

Early in 1942 the Interstate Commerce Commission authorized the rail and water carriers to increase the freight rates and charges on all commodities, with a few exceptions. The authorized increase on anthracite was in direct relation to the present rate. Specifically, on the present rate of $1.00 or less the increase approved was 3 cents per net ton and 4 cents per gross ton; on the present rate of over $1.00 the increases authorized were 5 cents per net ton and 6 cents per gross ton. Authorization for the increases was issued by the Interstate Commerce Commission on March 2, 1942, and the charges may become effective not later than May 15, 1942. The increases as approved apply to the war period and 6 months thereafter.

The anthracite industry had no major labor disturbances in 1941, although several thousand miners in the lower fields, especially in the Lehigh region, were away from work for about a month. The dissatisfaction of the miners was a union matter and concerned union dues and assessments. The wage agreement between the anthracite mine operators and the United Mine Workers of America, effected in May 1939, expired April 30, 1941. After a 1-day suspension, a new contract was arranged between the operators and the mine workers. The agreement became effective May 1, 1941, and expires April 30, 1943. The miners were given a compensation payment, with 1 week's vacation, and also received a graduated percentage increase over the old wage scale.

Research at the Pennsylvania State College School of Mineral Industries, which was begun in 1939 when the Miller bill passed the Pennsylvania General Assembly, was continued. The Miller bill expired on May 31, 1941, but enactment of the Williams-Kenehan bill continued the work until May 31, 1943. Research also was continued within the industry, where special efforts are being made to

find new uses for anthracite and more efficient utilization of that fuel in modern coal-burning equipment.

Definition of Pennsylvania anthracite industry.—Based upon differences in composition and characteristics of the product, trade practice and historical usage recognize two major divisions in the coal industry of the United States—bituminous coal and Pennsylvania anthracite. Anthracite and semianthracite also are mined in parts of Virginia, Arkansas, Colorado, and New Mexico. Locally these coals represent distinct and important industries, but the tonnages involved are small and for statistical convenience usually are grouped with the totals of the bituminous-coal industry.

The Pennsylvania anthracite industry, as here defined, includes all nonbituminous fields of that State. Trade usage commonly includes the output of the Bernice Basin in Sullivan County with Pennsylvania anthracite, although the coal of this basin is classified officially as semianthracite.

Statistical trends.—Tables 1 and 2 present statistical data on the Pennsylvania anthracite industry.

The war and anthracite.—Pennsylvania anthracite contributes to the war program chiefly on the home front. It is primarily a domestic fuel and is used for heating homes and apartment houses, as well as for hot water and cooking purposes; moreover, Army camps are using considerable quantities. The homes of thousands of war workers are made comfortable by this fuel, which contributes in this way to the moral and physical well-being of those employed in vital industries. It has similar uses in Canada, to which the United States exports large quantities, mostly domestic sizes for heating homes and small apartment houses. Anthracite is also consumed by public utilities, railroads, and manufacturers connected directly or indirectly with the production of war materials.

The Pennsylvania anthracite industry would be able to increase its output substantially whenever necessary if there should be any disruption in the continued supply or flow of other fuels, such as bituminous coal, coke, and oil, to the New England and Middle Atlantic States. Many of the small heating plants in that area, which now burn coke or oil but at one time used anthracite, can be converted at relatively small expense to use that fuel again. Then too, the anthracite regions are much nearer the highly populated areas of the New England and Middle Atlantic States than are the bituminous-coal and oil fields; if allocation of fuels is necessary, as in the First World War, anthracite may be drafted for more extensive service in both domestic heating and industry, where these fuels are now used.

In November 1941 the President requested that the Secretary of the Interior act as Solid Fuels Coordinator to take care of many difficult problems of production, distribution, utilization, and transportation of solid fuels. The defense and Lease-Lend programs created a large increase in the demand for anthracite and bituminous coal, and it was these fuels with which the Office of Solid Fuels Coordination was primarily concerned. The Bureau of Mines has cooperated closely with that office in its work on anthracite.

TABLE 1.—*Statistical trends of Pennsylvania anthracite industry, 1937–41*

	1937	1938	1939	1940	1941
Production:					
Loaded at mines for shipment:

Anthracite program.—Producers whose output comprised a large proportion of the total tonnage of the anthracite industry continued to operate under the voluntary production-control program inaugurated early in 1940 and sponsored by the Commonwealth of Pennsylvania, the operators, and the United Mine Workers of America.

In accordance with the Act of General Assembly No. 125, July 1941, the Commonwealth of Pennsylvania, Department of Commerce, having received petitions signed by producers whose output was more than 95 percent of the total anthracite production and by the United Mine Workers of America, adopted the Anthracite Emergency Program as a production-control plan for the anthracite industry. The order became effective November 10, 1941, when the Secretary of the Pennsylvania Department of Commerce began to administer the program. The Anthracite Emergency Committee is now known as the Anthracite Committee.

For several years before the plan was adopted, the industry was in a demoralized state owing to inroads of other fuels and keen competition for the anthracite markets within the industry itself. The primary purpose of the plan was to create some degree of stabilization within the industry and to bring production in closer alinement with current demand. The plan is credited with having helped to bring about this condition. The illicit or "bootleg" mining of anthracite and its marketing created a highly unfavorable condition in the hard-coal regions and in the market territory where the coal was sold. The Anthracite Committee has helped to alleviate this problem by making arrangements for the legitimate industry to buy the "bootleg" product and wherever possible to employ former miners of illicit coal.

Federal Anthracite Coal Commission.—In December 1941 the President approved House Joint Resolution No. 255 creating the Federal Anthracite Coal Commission. The Commission was composed of two members of the Senate, two members of the House of Representatives, the Director of the Federal Bureau of Mines, an employee of the National Resources Planning Board, and an employee of the Interstate Commerce Commission. The Commission was to determine facts relating to and investigate ways and means for improving economic conditions in the anthracite-producing regions of the United States. After hearings in the Pennsylvania anthracite regions and study of special reports from Federal, State, and local Government agencies, civic organizations, and private citizens, the Commission in April 1942 submitted its report to the President and the Congress. The report contained recommendations for both short-term and long-term measures of improvement.

Recommendations for immediate improvement called attention to the unused manpower and housing facilities in the anthracite regions and suggested that consideration be given to the establishment of war plants and industries of more permanent nature. Vocational schools were mentioned as a means of educating persons in the specialized training required by war industries. The report urged that surveys of mine flooding should be pressed to completion and that the industry should continue development of stokers and automatic equipment and investigate ways to expand industrial uses for anthracite.

As regards long-term improvement, it was suggested that a Federal Bureau of Mines research station be established in the anthracite area to develop new and extended uses for anthracite, study methods of mining, and coordinate activities of Pennsylvania State and local agencies with those of the United States Government. It was also suggested than an economic survey be made concerning the possibilities of reforesting the anthracite area and that an agency be created to deal with economic problems resulting from gradual depletion of anthracite reserves.

Illicit coal.—The illicit or "bootleg" mining of anthracite, which was begun in the early 1930's when unemployed miners dug coal from land owned by anthracite-operating companies, continued in 1941, when about 5 million tons of coal were produced by activity of this type. In 1936 illicit production totaled about 2½ million net tons; and, according to the Anthracite Institute, that for 1940 totaled more than 4 million tons. Early in 1941 the Anthracite Committee adopted a plan, the successful operation of which it was hoped would eliminate this kind of mining. For example, it provided that any cooperating producer may make lawful arrangements to purchase the output of a "bootleg" hole or holes in addition to his own quota (assigned under the emergency program), which will not be affected thereby. Coal bought in accordance with this agreement is included in the production statistics of this chapter. The plan provided also that cooperating producers may employ former "bootleggers," and such producers are granted a supplemental allocation equal to 3¼ net tons per man per day of commercial output for each man so employed.

According to a survey by the Anthracite Emergency Committee (now the Anthracite Committee) in March 1941, 10,762 men were working in 3,006 "bootleg" holes, whereas in May 1942 a comparable survey revealed 7,554 men employed in 2,029 holes—a reduction of 30 percent in men and 33 percent in the number of holes being operated. Some of this decrease probably can be attributed to efforts of the Anthractie Committee to eliminate this undersirable type of mining. Then, too, the heavy demand for men due to the accelerated industrial activity and restrictions on automotive equipment undoubtedly has tended to decrease the mining of "bootleg" coal. It is expected that the output from illicit mines will be much less in 1942 than in 1941.

Research and technologic developments.—The annual anthracite conferences have been recessed for the duration of the war because of the present great demands on the time of technical men. The fifth such conference was originally scheduled to be held at Lehigh University on May 7 and 8, 1942. Many fine papers on research and technologic developments in the anthracite industry have been presented at these conferences in the past. The fourth annual conference, at Bethlehem in May 1941, is discussed briefly in Minerals Yearbook, Review of 1940.

The cooperative research program, sponsored by the Commonwealth of Pennsylvania and the anthracite industry at the Pennsylvania State College, was continued. Among other subjects, special attention was paid to the use of anthracite in water-gas generators and the preparation of activated carbon from Pennsylvania anthracite.

Experiments concerning the resistance of anthracite to mechanical and thermal shock were also conducted.

In the nineteenth century, anthracite was employed extensively in foundries and blast furnaces as metallurgical fuel; in 1890 alone, 2,186,411 gross tons of pig iron were made using anthracite as fuel. Considerable research and experiments have been under way within the industry for the last several years in an attempt to revive this one-time important industrial use for anthracite. Experiments also are being conducted on the possibility of using anthracite culm and ashes in the manufacture of lightweight aggregate to be used in concrete construction materials. Studies are being made concerning the use of anthracite for soil improvement and the production of mineral wool from anthracite culm and ashes.

Anthracite Industries, Inc., conducted extensive investigations concerning oil-burner installations and factors to be considered in connection with conversion from oil to anthracite, with special reference to the possible shortage of petroleum products along the Atlantic seaboard. Research was continued in the Anthracite Industries laboratory on more efficient utilization of anthracite in automatic burning equipment.

Anthracite Institute.—The Anthracite Institute, through its information services, kept the industry informed on many Federal, State, and local matters concerning anthracite. Members of the institute staff appeared before various groups in the interest of the anthracite industry. It was particularly active in voicing its opposition to hydroelectric projects that might interfere with the consumption of anthracite and also actively disapproved the extension of natural-gas lines into the primary anthracite markets.

Distribution.—During the First World War, the distribution of Pennsylvania anthracite in the United States covered a wider area than in 1941. In the coal year 1916–17 anthracite was shipped to 44 States and to the District of Columbia, whereas in the calendar year 1941, according to the Pennsylvania State Department of Mines, shipments were made to 42 States and to the District of Columbia. Not only has the area of distribution changed, but the percentage of shipments to various sections has definitely changed. For the coal year 1916–17 the New England and Middle Atlantic States received 75 percent of the total anthracite shipped to destinations in the United States, whereas in 1941 this same group of States received 94 percent. Details of anthracite distribution for the coal year 1916–17 and the calendar year 1941 are given in tables 3 and 7.

According to the Commonwealth of Massachusetts, Division on the Necessaries of Life, rail receipts of Pennsylvania anthracite in New England in 1941 were 4,869,640 net tons. Tidewater receipts in 1941, including imports during the first 9 months of the year, were 681,733 tons. Table 4 gives details of anthracite movement into New England.

TABLE 3.—*Pennsylvania anthracite sold in coal year April 1, 1916, to March 31, 1917, in net tons*

[2] Department of Commerce.
[3] Total receipts by rail and by tide less imports.
[4] Revised figures.
[5] Preliminary figures.
[6] Figures cover January to September, inclusive.

Loadings at Lake Erie ports increased from 430,192 net tons in 1940 to 536,490 in 1941, or 25 percent. Receipts at Duluth-Superior increased 84 percent and those on the Upper Lake docks 29 percent.

Figure 1 illustrates graphically shipments of anthracite from the Lehigh, Schuylkill, and Wyoming regions, 1850–1940.

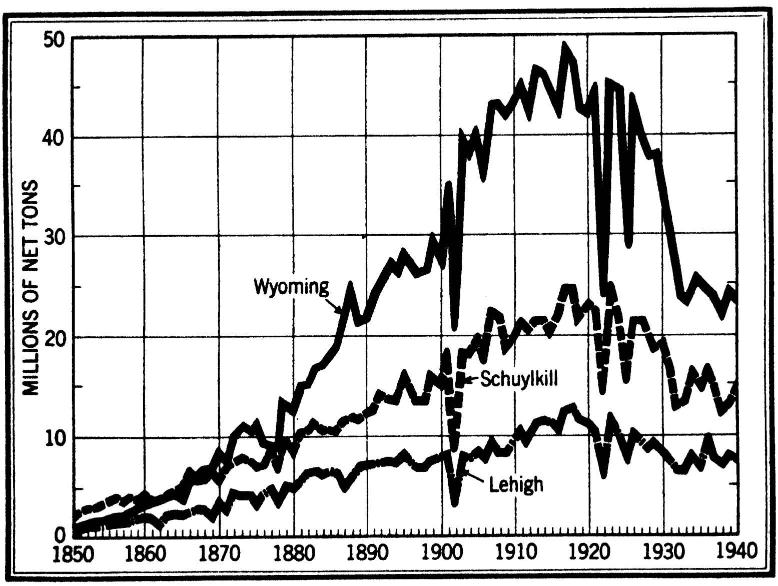

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1850–1940.

Competitive fuels in the United States and in principal markets.—The principal anthracite markets today are the New England States, New York, New Jersey, Pennsylvania, Maryland, Delaware, and the District of Columbia. Data on the consumption of all fuels in these markets are not available; however, the apparent consumption of anthracite, coke, briquets, and heating and range oils, in terms of anthracite, amounted to 80,615,000 net tons in 1940. The sales of heating and range oils in this area in 1940 were the equivalent of 32,543,000 tons of coal, and the mine shipments of anthracite to these States were 43,718,000 tons. According to the Pennsylvania State Department of Mines, anthracite shipments in 1941, rail and truck, to this area totaled 47,466,000 tons. In addition, considerable quantities of "bootleg" or illicit coal were shipped into these markets. The demand for coke for metallurgical use was chiefly responsible for the decline in its consumption for domestic heating from 4,052,000 tons in 1940 to 3,688,000 tons in 1941. Details are shown in table 5.

In general, the supplies of fuel commonly used for space-heating purposes in the United States increased in 1941 over 1940. The increase in anthracite was quite pronounced, but estimates for sales of heating and range oils show only minor gains when compared with the large increase in 1940 over 1939. Sales of byproduct and beehive coke for domestic heating decreased about 19 percent in 1941 compared with 1940. Details on the supplies of various fuels are given in table 6.

Transportation of anthracite to principal markets.—Anthracite all-rail and truck shipments from the mine to destinations in the United States increased 8 percent in 1941 over 1940, according to data compiled from records of the Pennsylvania State Department of Mines. Rail shipments increased 6 percent; truck shipments, 22 percent. Of the total shipments in 1941, the railroads hauled 85 percent and trucks 15 percent. In 1940, of the total shipments, 86 percent moved by rail and 14 percent by truck; in 1939 the percentages were 89 and 11 percent, respectively.

Pennsylvania received 66 percent of the total truck shipments in 1941; New Jersey and New York followed with 18 and 14 percent, respectively. It is also of interest to note that of the 7,529,479 tons trucked in 1941, 3,252,787 tons were handled in January, February, March, and December.

The trucking of anthracite from the mines has more than doubled since 1936, when the tonnage totaled 3,177,656. It is questionable, however, whether transportation by this method will continue throughout 1942 at the 1941 rate with war restrictions on rubber tires and other vital materials.

The distribution of rail shipments of anthracite, by States of destination, for 1939–41 is shown in table 7, and truck movement of Pennsylvania anthracite by months in 1941, by States of destination, in table 8.

TABLE 5.—*Apparent consumption of anthracite and selected competitive fuels in the principal anthracite markets, 1938–41*

[1] Pennsylvania Department of Mines; illicit coal not included.
[2] An important but undetermined part of anthracite shown as shipped to New Jersey is reshipped to New York City.
[3] Data not yet available.
[4] Department of Commerce; 1941 totals cover January to September, inclusive.
[5] Less than 1,000 tons.
[6] Less than 0.05 percent.
[7] Estimated upon basis of distribution in 1936.
[8] Converted to coal equivalent upon basis of 4 barrels of fuel oil equaling 1 ton of coal.
[9] Excludes bituminous coal.

Consumption.—War-time restrictions limit the publication of import and export statistics for 1941 to the first 9 months of the year. Taking this into consideration and making allowances for changes in producers'stocks, the consumption of anthracite in the United States in 1941 amounted to 53,700,000 net tons, an increase of about 4,700,000 tons over the calculated consumption in 1940. Changes in retail dealers, and small consumers' stocks are not included in these calculations, as data on variations are insufficient. Class I railroads and electric power utilities consumed 4,287,481 net tons of anthracite in 1941 compared with 3,804,209 tons in 1940.

TABLE 6.—*Total supplies of fuels commonly used for domestic purposes in the United States, 1924 and 1938–41*

[Wherever available, figures represent quantity actually consumed for domestic heating or for heating offices, apartments, hotels, schools, hospitals, etc. Where such figures are not available but where the fuel is known to be used chiefly for domestic purposes, total production (or imports) is shown to indicate trend of growth]

[1] A considerable part of Buckwheat No. 1 and smaller steam sizes is used by industries, railroads, and public utilities.
[2] Figures cover January to September, inclusive.
[3] Production plus imports less exports. Import and export figures for 1941 cover January to September, inclusive.
[4] Subject to revision.
[5] Partly estimated.
[6] Data not available.
[7] An estimated one-half is used for domestic purposes.
[8] Exact data not available; estimated between 55 and 77 million tons a year, including lignite and anthracite and semianthracite outside of Pennsylvania, shown separately.
[9] Revised figures.
[10] Includes all grades of fuel oil used for heating buildings.
[11] Includes gas used for heating offices, hotels, apartments, schools, hospitals, and stores and other large buildings, as well as houses.
[12] American Gas Association.

Changes in stocks.—Producers' stocks totaled 1,273,788 net tons on December 27, 1941, and 939,227 tons on December 28, 1940.

Stocks held by 164 selected retail dealers totaled 338,797 tons in January, reached a low of 248,206 tons in March, and increased to a high of 532,196 tons in November.

[1] Compiled from reports of Pennsylvania Department of Mines.

On December 31, 1941, stocks of anthracite held by railroads (class I only), electric power utilities, and other industrial consumers amounted to 1,784,875 net tons, compared with 1,589,427 tons on the same date in 1940. Stocks held by the railroads increased 66 percent followed in order, with smaller increases, by other industrial consumers and electric power utilities.

The stocks of anthracite on the Upper Lake docks on December 31, 1941, amounted to 273,727 net tons—a substantial increase from the 217,970 tons on this date in 1940.

Trend of employment.—The average number of men employed in the Pennsylvania anthracite industry in 1941 was 88,054, which is comparable with a total of 91,313 men in 1940. Men working in "bootleg" or illicit mining are not included in these figures.

Trend of prices.—Circular f. o. b. mine prices as quoted by leading anthracite-producing companies in trade journals were firm throughout 1941 and contrasted sharply with the chaotic price situation in 1939. The prices in January 1941 were as follows: For Broken, Egg, Stove, and Chestnut, $6.25 a net ton; for Pea, $4.75 a ton. In June, prices on these sizes advanced 10 cents a ton, and additional increases in July, August, and September raised them to $6.75 a ton for Broken, Egg, Stove, and Chestnut and $5.25 a ton for Pea. At the close of 1941, the prices for these sizes had not changed from the September quotations. In January, Buckwheat, Rice, and Barley were quoted at $3.50, $2.75, and $2.00 a ton, respectively. In May the prices on these sizes advanced to $3.75, $2.90, and $2.15 a ton and were still at this level when the year ended.

During 1941 several conferences concerning anthracite prices were held between representatives of the anthracite industry and members of the Office of Price Administration. After the September advance in prices, the producers agreed to make no further increases without consulting the Office of Price Administration.

According to the Bureau of Labor Statistics, Department of Labor, the retail prices for Stove size on December 15, 1940, in Boston, New York City, Buffalo, Philadelphia, and Washington, D. C., were $13.75, $11.72, $11.72, $10.40, and $12.95 a net ton, respectively. On the same date in 1941, comparable prices were $14.50, $12.35, $12.38, $11.64, and $13.70 a ton. At the same periods, the prices for Buckwheat No. 1 in these cities were $10.00, $8.38, $8.48, $7.75, and $9.60 in 1940 compared with $11.00, $8.48, $8.73, $8.50, and $10.00 in 1941.

The prices apply to a net ton of 2,000 pounds except in the District of Columbia, where the gross ton of 2,240 pounds is used. New York City prices include a 2-percent sales tax in 1940 and 1 percent in 1941.

Sales realization.—The average realization on breaker shipments increased from $4.27 a net ton in 1940 to $4.59 in 1941, an increase of 7 percent. The average value per net ton of the total anthracite production in 1941 was $4.26 compared with $3.99 in 1940.

Imports and exports.—As previously mentioned, war restrictions permit publication of import and export statistics on anthracite in 1941 for the first 9 months only. For the January–September period of 1941, exports of Pennsylvania anthracite amounted to 2,416,104 net tons valued at $19,657,920. Exports for the entire calendar year 1940 totaled 2,667,632 tons valued at $21,210,499. Imports of anthracite for the first 9 months of 1941 amounted to 64,267 net tons, whereas in the entire calendar year 1940 imports were 135,436 tons. In both periods all the imported coal came from Canada and the United Kingdom. (See tables 36 and 37.)

497779—43——60

Mechanical stokers and oil burners.—According to the Bureau of the Census, Department of Commerce, factory sales of mechanical stokers for burning anthracite increased 28 percent in 1941 over 1940. Sales of class 1 stokers (capacity under 61 pounds of coal an hour) increased from 12,837 units in 1940 to 17,110 units in 1941. Sales of class 2 stokers (capacity 61 to 100 pounds of coal an hour) decreased from 970 units in 1940 to 599 in 1941.

In 1941, 303,869 oil burners were shipped compared with 264,232 in 1940—an increase of 15 percent. These figures include both domestic and foreign shipments but do not include burners used in ranges, stoves, water heaters, and space heaters.

SOURCES AND ACKNOWLEDGMENTS

Final statistics of the Pennsylvania anthracite-mining industry are prepared from an annual canvass, by mail, of all known legitimate anthracite operations that are active producers. More than 95 percent of the tonnage is reported direct, and the remainder is collected by personal visits or from reliable collateral evidence. The data on individual operations furnished by the producers are voluntary and confidential, as is customary in the statistical services of the Bureau of Mines.

In assembling available detailed information, free use has been made of pertinent figures prepared by the Anthracite Institute, the Anthracite Committee, the American Association of Railroads, and the Pennsylvania Department of Mines; the cordial and continued cooperation of all of these and of others from whom information has been received is gratefully acknowledged. Especial thanks are also due to the producers for reporting so promptly and, in general, so fully regarding their operations during 1941.

PRODUCTION

The output of Pennsylvania anthracite in 1941 totaled 56,368,267 net tons—a substantial increase over the 51,484,640 net tons produced in 1940. For historical comparison, these figures include a small amount of semianthracite produced in Sullivan County (37,020 net tons in 1941). Included also is the production of river coal, which is recovered by dredging from the streams draining the anthracite fields. This source supplied 1,517,563 net tons in 1941.

Before 1941 the Bureau had not considered the production of "bootleg" or illicit coal in its statistics on the Pennsylvania anthracite industry. The output from unauthorized mines has been considerable, and in 1941 totaled about 5,000,000 tons, of which about 2,000,000 tons were purchased by the legitimate industry and included in the production statistics in this chapter. In an effort to eliminate this undesirable condition, the legitimate industry (through the Anthracite Committee) decided upon a plan whereby it would lawfully buy the output from "bootleg" holes and at the same time attempt to employ the miners working the "bootleg" operations in the legitimate mines. This plan was put into effect in the first part of 1941; during the course of the year, the legitimate operators purchased run-of-mine coal from the bootleggers and shipped 1,902,481 tons of the prepared product to market. It would be very difficult if not impossible to segregate this purchased "bootleg" production from the output of

the legitimate industry, and it is therefore included in the various production tables in this chapter. Because of the inclusion of this quantity of illicit coal, the production statistics for 1941 are not exactly comparable with previous years. No attempt has been made to include in the statistics any other illicit coal than that purchased by legitimate operators.

Weeks and months.—Tables 9 and 10 summarize the statistics of weekly and monthly production of anthracite. Statistics of current output are estimated from records of car loadings and other pertinent data. The weekly and monthly figures in tables 9 and 10 have been adjusted to the annual total ascertained by direct canvass of the operators.

[1] Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Monthly statistics from 1905 to 1925 will be found in Mineral Resources, 1925, pt. II, pp. 427–428, and from 1926 to 1930 in Mineral Resources, 1930, pt. II, p. 741.

[2] Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.

Small mines and intercompany sales.—All known legitimate operations are included in the statistics. In recent years conditions have favored the development of numerous small mines operating on lease or subcontract and producing run-of-mine coal, which is sold to larger companies for preparation at a breaker. At the same time, an increasing transfer of coal from one operation to another has developed, and some of the companies have built central breakers to which coal from numerous mines is shipped, by rail or truck, for preparation. These tendencies have increased the complexity of the task of collecting and compiling statistics of the industry; but great care has been exercised to avoid double counting of tonnages produced by one operator and prepared for market by another, and the figures herein represent the net quantity of merchantable coal plus the fuel used by the collieries themselves. The employees of legitimate operators producing run-of-mine only have been included in the employment statistics, as they have received wages from the industry and have contributed to the final product.

Regions, fields, and counties.—The anthracite fields are divided into three trade regions—Lehigh, Schuylkill, and Wyoming. This classification is generally used by the trade, and it is also followed in the district organization of the United Mine Workers of America, in which District 1 corresponds to the Wyoming region, District 7 to the Lehigh region, and District 9 to the Schuylkill region. Geographically the anthracite area is classified by fields—the Northern, Eastern Middle, Western Middle, and Southern. This classification is used in technical operating studies because it follows more closely the geologic conditions that largely influence the methods and cost of mining. The Northern field is the same as the Wyoming region. The Lehigh field and that part of the Southern field lying east of Tamaqua (known as the Panther Creek Valley) make up the Lehigh region. The Schuylkill region comprises the Western Middle field and that part of the Southern field lying west of Tamaqua. For historical comparison, the tonnage of the small Bernice Basin is often included with the statistics of the Northern field, although the coal is classified officially as semianthracite. The total area of the four fields is about 484 square miles—the Northern covers 176 square miles, the Eastern Middle 33, the Western Middle 94, and the Southern 181.

Based upon the quantity of minable reserves, the Southern field is first, followed by the Western Middle, Northern, and Eastern Middle.

Tables 11 to 13 present production data by regions, fields, and counties.

Culm-bank coal.—In the early days of anthracite mining, the smaller sizes of anthracite—especially Pea and smaller—were not used, as they are today, and these sizes and larger pieces of refuse containing much good coal were piled in large banks throughout the region. In 1879 the recovery of the sizes smaller than Pea coal was less than 1 percent of all sizes made, but in 1940 these sizes comprised 34 percent of the total breaker shipments. In recent years, with the increased demand for the smaller sizes and the use of modern and efficient preparation methods, material from the culm banks is run through washeries or breakers, and a clean, prepared coal is obtained. This source supplied 2,783,038 tons in 1940 and 3,656,866 tons in 1941. Tables 14 and 15 give a detailed break-down of culm-bank production, by regions and fields.

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.
[2] Counties producing dredge coal only.

Reconciliation of fresh-mined, culm-bank, and breaker product.—Anthracite is now produced from three sources—mines (including strip pits), culm banks, and the rivers and creeks that drain the

anthracite region. As all three sources contribute to the country's supply, it is necessary to consider them all to ascertain the total production. No difficulty is experienced in separating the figures of production by dredges, as this is a distinct industry. It is difficult, however, to make a sharp differentiation between fresh-mined and culm-bank coal that can be maintained throughout the statistics of the industry.

TABLE 14.—*Pennsylvania anthracite produced in 1941, classified as fresh-mined, culm-bank, and river coal and as breaker, washery, and dredge product, by regions, in net tons*

As the best solution of this problem, the individual breaker, washery, or dredging operation is taken as the unit in compiling the statistics, and the producing companies are asked to supply separate statements for each type of plant. These are totaled to form the primary tables of this report to show the total quantity of breaker product, washery product, and dredge product, with related figures of value and number of employees.

The figures from breaker and washery plants, however, are not exactly equivalent to the fresh-mined and culm-bank coal because of the practice, sometimes adopted, of putting culm-bank coal through a breaker, either directly from the bank or after preliminary treatment in a washery. The tonnage of culm-bank coal prepared at the breakers is broken down by fields and shown in table 16.

Interregional variation in sizes.—Geologic conditions affect the percentages of domestic and steam sizes produced and consequently the value of the product as a whole. In the Wyoming and Lehigh regions,

the percentage yield of the higher-priced domestic sizes is relatively high; in the Schuylkill region, it is less because of the crushing of the coal by faulting and folding of the beds. In 1941, the breaker output of the Wyoming region comprised 70.2 percent domestic sizes and 29.8 percent steam sizes; the Lehigh region—62.8 percent domestic and 37.2 percent steam sizes; the Schuylkill region—57.7 percent domestic and 42.3 percent steam sizes. Table 17 shows shipments of anthracite by regions and sizes. Table 18 shows by regions the percentages of various sizes in relation to total breaker product.

[1] Quantity of Lump included is insignificant.
[2] Includes all steam sizes.
[3] Some Silt included in Buckwheat No. 4.

AVERAGE SALES REALIZATION

The valuation figures in this study represent value at the breaker or washery reported by the operating companies. The company is requested to "estimate value of the product not sold" and to "exclude selling expenses" in making its report.

From this it will be seen that when a producing concern sells its output to a separately organized sales company, the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the general market. This fact should be borne in mind in considering the variations in value among different regions, shown in the tables, for the same sizes of coal.

The average sales realization per net ton on breaker shipments was $4.59 in 1941 compared with $4.27 in 1940 (see table 19). If local sales, colliery fuel, and washery and dredge coal are included, the average value per net ton of the total 1941 production was $4.26 compared with $3.99 in 1940 (see table 20).

TABLE 19.—*Average sales realization per net ton on Pennsylvania anthracite shipments from breakers, 1939–41, by regions and sizes*

Grand total	4.14	3.71	1.26	3 99	4.41	4.01	1 45	4.26

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

LABOR STATISTICS

The peak year for employment in the Pennsylvania anthracite industry was 1914, when 179,679 men were employed; in 1917, the year of largest output, the number was 154,174. The average number of men employed in 1941 was 88,054, a decrease of 3,259 from the 91,313 employed in 1940 (see tables 21 and 22). The number employed is based upon reports by the operators and includes the workers from strip-pit and dredge operations.

These statistics do not consider the men and boys working in "bootleg" or illicit coal mining, which has increased in output considerably since its start in the early 1930's. Before 1941, production statistics of the Bureau did not include "bootleg" coal; however, in 1941 many legitimate operators purchased run-of-mine coal from the "bootleggers," prepared it at their breakers for shipment to market, and, in their annual reports to the Bureau, included this purchased coal with the legitimate output. It would be very difficult to obtain employment data for the holes from which this "bootleg" coal was dug. Therefore, in calculating the output per man per day, the tons of "bootleg" purchased were deducted from the total output as reported by the operators, and the resulting legitimate production was then used to calculate the output per man per day. Part of the time of the preparation men in legitimate plants was, of course, required for preparing the illicit product; however, on a per-ton basis this time is very small, and its omission will not detract materially from the validity of the result obtained.

Although there were no major labor disturbances in 1941, several thousand miners in the Schuylkill and Lehigh regions were away from work for about a month because of some dissatisfaction concerning union dues and assessments. The number of man-days lost because of strikes totaled 176,432 and 397,616 in 1940 and 1941, respectively, and the average days lost per man employed in the industry was 1.9 and 4.5 in these respective years (see table 23).

According to the Bureau of Labor Statistics, average weekly earnings in 1941 ranged from a low of $16.43 in April to a high of $34.20 in June and were $27.41 for the year as a whole compared with $24.95 in 1940. The index of employment (1929 average=100) fluctuated between 48.6 percent in May and 50.6 percent in February and for the year as a whole averaged 2 percent below 1940. The index of pay rolls (1929 average=100) reached a low of 24.3 in April and a high of 51.2 in June and averaged 7.5 percent above 1940.

EQUIPMENT AND METHODS OF MINING

Mechanical loading.—The quantity of coal loaded mechanically underground increased from 12,326,000 net tons in 1940 to 13,442,000 tons in 1941. Hand-loaded tonnage also increased in 1941 over 1940, but upon a percentage basis the gain in mechanically loaded coal was greater than the increase in the hand-loaded anthracite. Details of mechanical loading, hand loading, and stripping are given in tables 24 to 26. Figure 2 illustrates the relative growth of mechanical loading, hand loading, and stripping in the Pennsylvania anthracite region, 1927–41.

TABLE 24.—*Relative grouth of mechanical loading, hand loading, and stripping in Pennsylvania anthracite mines, 1937–41*

[Mechanical loading includes coal handled on pit-car loaders and hand-loaded face conveyors]

Year	Net tons: Mechanical loading underground	Net tons: Stripping	Net tons: Hand loading	Index numbers: 1927=100: Mechanical loading underground	Index numbers: 1927=100: Stripping	Index numbers: 1927=100: Hand loading

Strip-pit operations.—Strip-pit tonnage increased from 6,353,000 net tons in 1940 to 7,317,000 in 1941. In 1941 more than half of the stripping tonnage was recovered from pits in the Schuylkill region, and the Lehigh and Wyoming regions followed in order of output. For details of anthracite mined from strip pits see table 28. Figure 3 illustrates graphically the production of anthracite from strip pits, by regions, 1927–41.

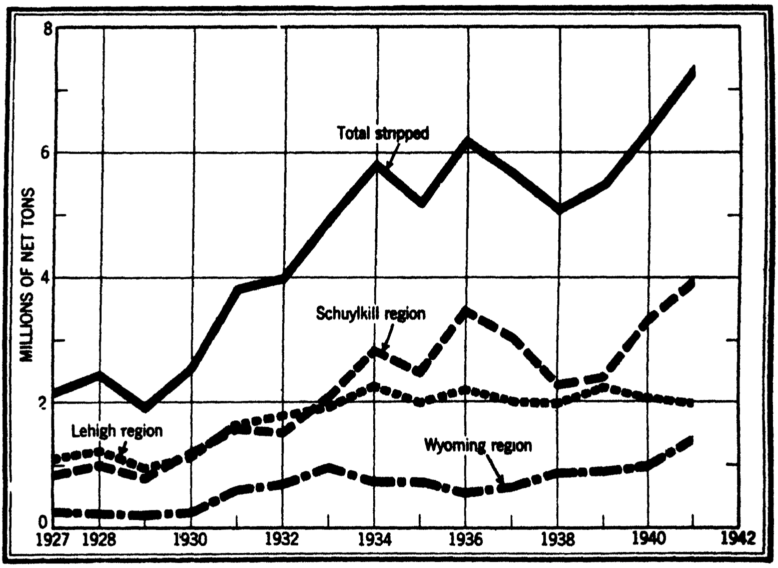

FIGURE 3.—Pennsylvania anthracite mined from strip pits, by regions, 1927–41.

[1] Certain equipment reported by stripping contractors may have been counted twice when moved from one small job to another during the year. The amount of such double counting is unknown but presumably is not great.
[2] Data not available.

"RIVER" OR "DREDGE" COAL [2]

Review of the river-coal industry.—The rivers and creeks that traverse the anthracite fields of Pennsylvania have been dredged for "river" or "dredge" coal since about 1890. The principal rivers draining the fields, where dredging is being carried on, are the Susquehanna, Schuylkill, and Lehigh. Several creeks—the Shamokin, Mahanoy, Wiconisco, and Swatara—also are productive sources of river or creek coal. Operations along the streams cover a wide territory, and along the Susquehanna alone dredges are recovering coal for about 160 miles.

Early in the history of the Pennsylvania anthracite industry the small sizes of coal were not used as extensively as they are today. Grate, Egg, Stove, and Chestnut were the principal sizes shipped to market and used by the local trade. Pea and smaller sizes were not considered to have any great value and generally were discarded on culm banks with other refuse from cleaning, or they were washed into the rivers and creeks coursing through the anthracite fields. In recent years, with modern preparation methods and increasing demand for small sizes, the anthracite industry has recovered virtually all coal larger than Barley ($\frac{3}{16}$ by $\frac{3}{32}$ inch) and a substantial percentage of the still smaller sizes. Consequently, not nearly as much coal is deposited in the streams today as in the early days of the industry.

As stated, river coal was first dredged in the 1890's, but the earliest production reports received by the Geological Survey were for 1909. From 1909 to 1940, inclusive, dredge operators reported—to the Geological Survey and subsequently to the Bureau of Mines—the recovery of 17,624,533 net tons. Although this is only a small fraction of the total output of anthracite, it is important from the standpoint of conservation of natural resources. In 1940 this source supplied 942,944 tons of anthracite valued at $1,097,000.

[2] For detailed information on "river" or "dredge" coal, reader is referred to Corgan, Joseph A., Dredging Pennsylvania Anthracite: Bureau of Mines Inf. Circ. 7213, 1942, 25 pp.

Early river-coal operations.—The first commercial operations to recover river anthracite were begun in the Susquehanna River in the 1890's, when sand and gravel producers working the Susquehanna recovered coal as a byproduct.[3] It is quite likely that private individuals living along the rivers and creeks recovered by hand some of the large sizes, such as Chestnut and Pea, before 1890 for use in their homes. At that time heating and power plants were not equipped, as they are today, to burn the fine coal taken from the streams, and there was little demand for the product. When it became known that the dredged product could be used advantageously, the river coal became more popular, and industries and utilities began using it to generate steam.

Early preparation methods and sizes produced.—To show more clearly how anthracite came into the rivers and creeks, it is well to give a short résumé of the early methods used by the anthracite industry for cleaning and preparing the product for market.

Anthracite was first sold as run-of-mine, but it was not long before the producers realized that the coal was better-received by the public when it was sized and the small coal taken out. With the advent of breakers and shaking screens, the coal was sized more systematically; anything smaller than Stove was not considered marketable and was piled in culm banks outside the mine. These culm banks contained much good coal and over a period of years rainstorms washed part of the banks into the streams, adding to the river coal. The jigging or wet method of cleaning anthracite for market was introduced in the 1870's. The water used in wet cleaning carried large quantities of the smaller coal to creeks and rivers. In time, more efficient ways of using water to clean coal were devised, and there is no resemblance between the quantity of culm discharged in waste water now and that of 50 or even 25 years ago.

Statistics of production before 1890, by sizes, are not available for the entire anthracite region. Tables 29 and 30 reveal that in 1879 less than 1 percent of the coal smaller than Pea size was prepared for market. As shown in tables 29, 30, and 31, recovery of small sizes and a decline in percentage of Lump, Steamer, and Broken coal were underway in 1889.

TABLE 29.—*Sizes of Pennsylvania anthracite made by a producer in the Lehigh region, 1879 and 1889, in percent of total*

Size	1879	1889	Size	1879	1889
Lump and Steamer	15.8	8 91	Chestnut	17 4	15.58
Broken	19 4	16 69	Pea	15.2	14.27
Egg	15.9	13 13	Buckwheat and small coals	.5	18.07
Stove	15.8	13 35	Total for the producer	100.0	100 00

Table 32 gives statistics of sizes for the anthracite region in selected years. The definite trend from larger to smaller sizes is evident. Lump and Broken coal, which in 1890 constituted 25 percent of total shipments, were negligible in 1940, representing only 0.3 percent of the total product, whereas Buckwheat No. 1 and smaller, comprising

[3] Sisler, James D., Fraser, Thomas, and Ashmead, Dever C., Anthracite, Culm, and Silt: Pennsylvania Geol. Survey, 4th ser., Bull. M-12, 1928, p. 168.

10 percent of the shipments in 1890, amounted to 36 percent of the shipments in 1940. It is apparent from these tables that sizes considered unmarketable years ago are now treated as valuable and comprise a large percentage of the anthracite shipped.

TABLE 30.—*Sizes of Pennsylvania anthracite made by a producer in the Wyoming region, 1879 and 1889, in percent of total*

Size	1879	1889	Size	1879	1889

Production.—River-coal statistics were published first by the Geological Survey in 1909, when the output reported by dredge-coal operators was 107,788 net tons. In 1940 production as reported to the Bureau of Mines was 942,944 tons, with an indicated value of $1,097,000. The total output reported from 1909 to 1940 to the Geological Survey and subsequently to the Bureau of Mines was 17,624,533 net tons. Statistics for some of the early years may not have been complete, because many of the dredge operations were small and the operators could not be reached easily by correspondence.

As shown in table 33, the first year in which statistics were reported by rivers (including tributaries) was 1923, when the total production was 956,368 net tons valued at $811,065. It is to be noted that in 1923, as in every succeeding year to date, the output from the Susquehanna River and its tributaries was far greater than that of the Lehigh or Schuylkill Rivers.

TABLE 33.—*Pennsylvania anthracite produced by dredges, 1909–40, by rivers (including tributaries)*

[1] Data not available.
[2] Figures for value cover 1915–22.
[3] Schuylkill included with Lehigh in 1937, 1938, and 1940.

The average value per ton of the river product reached a high of $1.30 in 1918 and in 1940 was reported to the Bureau of Mines as

$1.16. These values are low compared with the value per ton of all Pennsylvania anthracite, which averaged $3.99 in 1940.

The average output per man per day in river-coal operations is much higher than in the anthracite industry proper; in 1940 it was 12.60 tons compared with 3.02 tons for the entire Pennsylvania anthracite industry.

According to Geological Survey records, of the total shipments of river coal in 1920, Buckwheat No. 3 and larger comprised 59.5 percent, whereas Buckwheat No. 4 and smaller represented 40.5 percent. In 1940 Buckwheat No. 3 and larger decreased to 46.3 percent of the shipped coal, and Buckwheat No. 4 and smaller increased to 53.7 percent.

Quality and uses.—The quality of river coal depends to a great extent on the preparation it receives after it is taken from the river. A large part of the river-coal output is not cleaned after the initial screening and washing, and it may contain some sand and gravel and be irregular in size, whereas the coal prepared over concentrating tables is clean and free from sand and gravel. Table 34 shows analyses of a combination of Barley and Buckwheat No. 4 coal dredged from the Susquehanna River near Harrisburg.

In the early days of the dredge industry, the sizes recovered were much larger than the coal taken from the rivers and creeks today; it was large enough so that considerable quantities could be used for domestic heating. As the methods of preparing coal at the breakers in the anthracite region were improved and new markets for the small sizes discovered, the coal finding its way into the rivers became smaller and smaller. In 1940, according to reports received by the Bureau of Mines, 83 percent of the river coal shipped was Buckwheat No. 3 or smaller. Domestic heating plants cannot burn such small coal without special equipment, and today virtually all of the river coal is sold for utility or industrial purposes.

TABLE 34.—*Proximate analyses of anthracite dredged from Susquehanna River, in percent*

[Air-dried; not tabled]

Sample	Moisture	Volatile matter	Fixed carbon	Ash	Total
1 [1]	3.6	6.6	68.8	21.0	100.0
2 [2]	3.3	6.9	71 4	18 4	100.0
3 [3]	3.5	6.7	73 9	15.9	100.0

[2] From river barges at Harrisburg.
[3] From river barges three-fourths of a mile north of Harrisburg.

TABLE 35.—*Pennyslvania anthracite produced by dredges in 1941, by rivers*

River (including tributaries)	Net tons	Value	
		Total	Average
Lehigh	47,838	$57,217	$1.20
Schuylkill	396,522	489,187	1.23
Susquehanna	1,073,203	1,293,380	1.21
	1,517,563	1,839,784	1.21

Operations in 1941.—In 1941 dredge operators reported a production of 1,517,563 net tons with a value of $1,839,784. For detailed statistics by rivers, see table 35.

FOREIGN TRADE [4]

Data on imports and exports of anthracite in 1941 may be published for the first 9 months only. During this January–September period, exports totaled 2,416,104 net tons, whereas in the full calendar year 1940 exports were 2,667,632 tons. Imports in the 9-month period of 1941 were 64,267 tons and in the entire year 1940 135,436 tons. It will be noted that in each year a small proportion of the imported coal came from Canada; this tonnage, no doubt, represents re-exports. Details of imports and exports are shown in tables 36 and 37.

TABLE 36.—*Anthracite imported for consumption in the United States, 1940–41, by countries and customs districts, in net tons*

	1940	1941 (Jan.-Sept.)
Country		
Canada	3,026	948
United Kingdom	132,410	63,319
	135,436	64,267

Montana and Idaho		45
Rhode Island	28,280	6,729
	135,436	64,267

TABLE 37.—*Anthracite exported from the United States, 1937–41*

Year	Net tons	Value
1937	1,914,173	$14,795,748
1938	1,908,911	14,634,504
1939	2,590,000	19,919,651
1940	2,667,632	$21,210,499
1941 (Jan.-Sept.)	2,416,104	19,657,920

Canadian market.—Coal and lignite production in Canada in 1941 totaled 18,222,107 net tons (a 3.7-percent increase over 1940).

Coal available for consumption in Canada (production, plus imports, minus exports) totaled 39,499,519 tons and exceeded the 1918 record by 4,078,179 tons or 12 percent. Imports of bituminous coal increased 32 percent over 1940 and 3.4 percent over 1918. The quantity of anthracite imported was 0.6 percent less than in 1940.

Outstanding features of the coal and coke industry and foreign trade of Canada in 1940 and 1941 are shown in table 38.

Imports of coal in 1941 increased 24 percent over 1940 and were 20 percent greater than Canadian coal production.

Nova Scotia mines, which supplied 40 percent of the coal and lignite produced in 1941, operated at approximately 82 percent of capacity; and Alberta, which produced 38 percent of Dominion output, operated at about 83 percent of capacity.

[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Under normal conditions a large part of Nova Scotia coal production reaches its markets by steamers up the St. Lawrence River. The war necessitated requisitioning these vessels for trans-Atlantic trade and thus increased the burden on the Canadian National Railway.

TABLE 38.—*Coal and coke industry and foreign trade of Canada, 1940–41,[1] in thousands of net tons*

COKE AND BYPRODUCTS

By Robert H. Ridgway, J. A. De Carlo, and M. M. Otero

SUMMARY OUTLINE

SUMMARY

Responding to the demands of the defense program, production of coke in 1941 exceeded all previous records. Output from byproduct ovens—58,482,422 net tons (see table 1)—was the highest on record, and that from beehive ovens—6,704,156 tons—was more than double the quantity produced in 1940.

The total output from byproduct ovens (see table 2) exceeded by 4,468,113 tons the previous maximum of 54,014,309 tons established in 1940 and represented an 8-percent increase. Impelled by the need for more coke in the iron and steel industry, beehive-coke production rose from 3,057,825 tons in 1940 to 6,704,156 tons in 1941, an increase of 3,646,331 net tons or about 119 percent. (See fig. 1.)

The dominance of byproduct ovens was again emphasized, for even during a year of peak activity in the steel industry they contributed 90 percent of all coke consumed and the beehive ovens 10 percent. Byproduct ovens operated at 92 percent of estimated capacity for the year compared with 86 percent in 1940.

The value of sales of coke, breeze, tar, and other byproducts in 1941 totaled $536,147,279 and exceeded the 1940 total of $442,282,951 by $93,864,328, an increase of 21 percent.

Prices of coke per net ton sold by the producers increased sharply over 1940. Average receipts per ton of coke sold by the producers were: Furnace coke, $5.63, an increase of $1.23 over 1940 (28 percent); foundry coke, $9.35, exceeded the 1940 figure by $1.07; coke used in the manufacture of water gas, $6.74 compared with $5.99 for 1940; and domestic coke, $6.93, an increase of $0.93 over 1940. Coke used for other industrial purposes, at $6.38, showed an increase of $0.96.

Coke screenings or breeze produced in 1941 totaled 4,554,513 tons and surpassed the 1940 production by 389,060 tons. The increase was accompanied by an increase in average receipts, as the $2.35 realized per ton was $0.11 higher than the amount received in 1940.

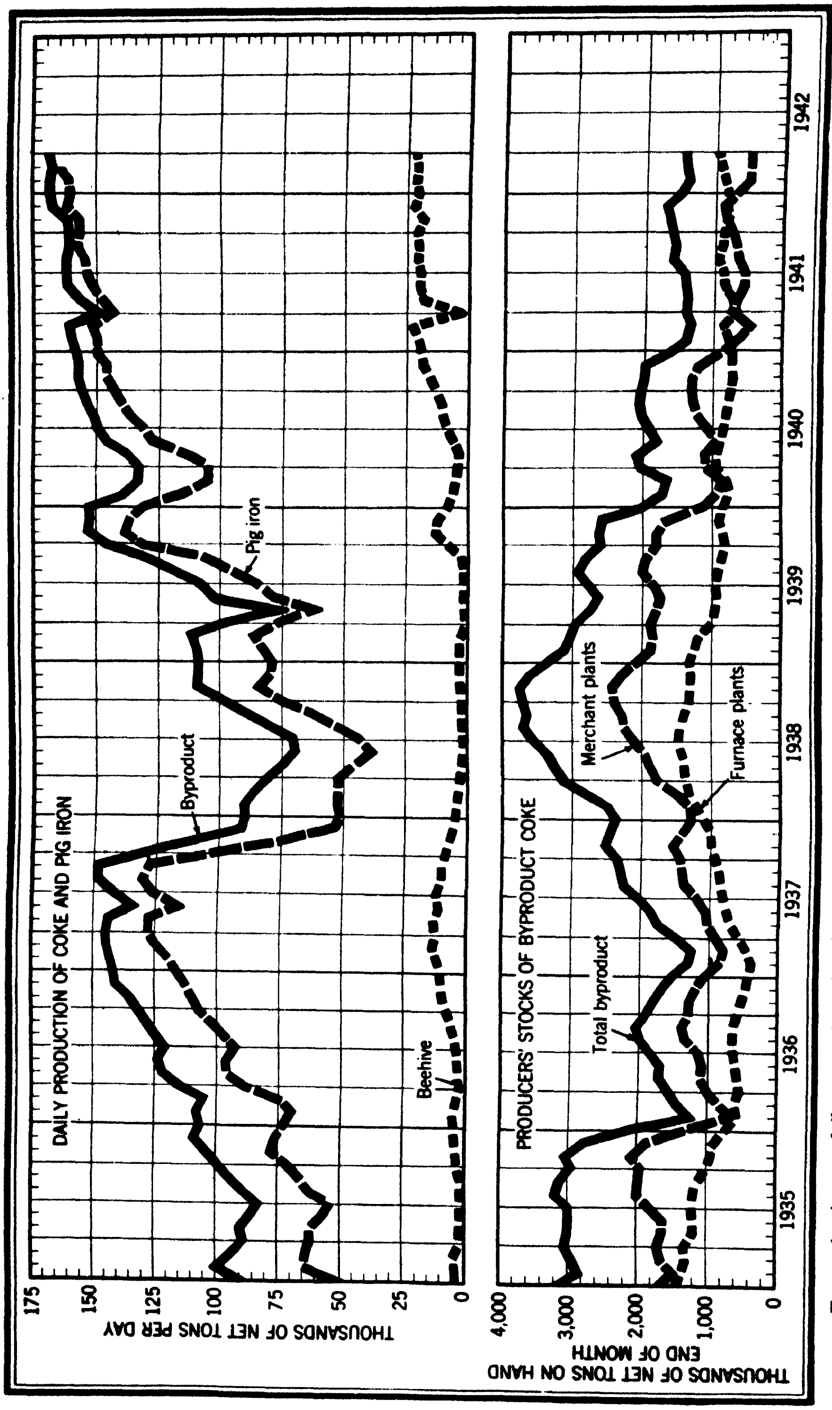

FIGURE 1.—Average daily production of beehive and byproduct coke and pig iron; and producers' stocks of byproduct coke, 1935–42, by months.

According to the principal uses to which it is put, coke may be classified as (1) blast-furnace coke; (2) foundry coke; (3) domestic coke; (4) coke for all other industrial uses, including water-gas coke. Coke used in blast furnaces totaled 50,454,325 net tons, an all-time high, compared with 42,483,624 net tons in 1940, an increase of 7,970,701 tons (19 percent). Coke sold for domestic purposes dropped 1,548,054 tons in 1941—6,682,959 tons against 8,231,013 tons in 1940—and emphasized the demand by the iron and steel industry. Sales of foundry coke increased sharply; 1941 sales of 2,846,459 tons exceeded the 1940 figure by 756,497 tons (36 percent). Coke sold for other purposes, including all other industrial uses, totaled 5,390,123 tons.

The consumption of coke in 1941 was the highest ever recorded—65,101,401 tons, or 8,075,155 tons above 1940.

The increased production of byproduct coke substantially increased the output of the major byproducts gas, tar, light oil, and ammonia. The average yield of each of the principal byproducts recovered per ton of coal carbonized declined a little from 1940, owing to shorter coking time. The unit prices received for the coke byproducts varied only slightly from those of 1940. The value of the coke byproducts produced was $158,809,184.

The total output of gas from byproduct ovens was 892,819,811 M cubic feet compared with 833,761,720 M cubic feet in 1940. Total tar produced amounted to 704,149,468 gallons compared with 673,286,517 gallons in 1940. Ammonium sulfate or equivalent showed a marked increase in production—1,741,503,884 pounds against 1,664,217,195 pounds in 1940. The output of crude light oil in 1941 surpassed the 215,213,667 gallons recovered in 1940.

Tables 1 and 2 present the principal statistical facts of the coke industry in 1941.

GOVERNMENT CONTROL MEASURES

During the calendar year 1941, activities of the Office of Production Management (now the War Production Board) relative to coke consisted in approving projects for new byproduct-coke plants necessary to supply blast-furnace coke for the expanded program of iron production for the iron and steel industries. In all, 443 new byproduct ovens were put into operation in 1941. Of these, 171 were constructed for merchant plants, 235 for iron and steel producers, and 37 for gas producers.

Maximum prices for byproduct foundry and byproduct blast-furnace coke were established in 1941 by the Office of Price Administration in Price Schedule 29, published September 20, 1941, in the Federal Register (No. 184, vol. 6, title 32, pp. 4821–4822). The prices became effective on and after October 1, 1941, and under general provisions (*a*) in appendix A of Price Schedule 29, the maximum prices of byproduct foundry coke are given for the various established coke markets.

Ceiling prices for byproduct foundry coke were established as follows:

Location of plant:	F. o. b. oven plant in cars (per net ton)
Alabama	$8.50
Ashland, Ky	10.00
Chicago, Ill	11.50
Detroit, Mich	11.75
Kearny, N. J	12.15
Buffalo, N. Y	11.75
Ironton, Ohio	10.00
Painesville, Ohio	11.25
Portsmouth, Ohio	10.00
Erie, Pa	11.75
Philadelphia, Pa	11.75
Chattanooga, Tenn	9.00
Fairmont, W. Va	10.00
Milwaukee, Wis	12.25

However, the complexity of the price structure was recognized; several exceptions to the general provisions were made and are shown in section (b) of appendix A. Amendment 1 of Price Schedule 29 was issued February 2, 1942, effective February 7, 1942, to describe the areas governed by specific oven prices so that they would conform with the industry's established practice; it did not affect the prices in Schedule 29. This amendment appeared in the February 4, 1942, issue of the Federal Register, (No. 24, vol. 7, title 32, p. 721). Appendix B of Price Schedule 29 outlines the maximum prices governing byproduct blast-furnace coke.

With only partial control of coke prices in effect, pressure was brought to bear upon the iron and steel industry by the rise in price of beehive-oven blast-furnace coke, which resulted in a thorough survey of the beehive-coke industry. As a result of study of the relationship between price and available supply of beehive coke, the Office of Price Administration in 1941 issued Price Schedule 77, which appeared in the Federal Register (No. 18, vol. 7, title 32, pp. 545-546) issued January 27, 1942, and effective on and after January 26, 1942. This price schedule established the maximum prices for beehive-oven furnace coke produced in Pennsylvania. Over 88 percent of the entire beehive-coke output was produced in Pennsylvania during the past year. Maximum prices on beehive coke other than Pennsylvania beehive blast-furnace coke were established by Maximum Price Schedule 121, effective May 18, 1942, which appeared in the Federal Register (Nos. 85–105, vol. 7, title 32, pp. 3237–3989 and 4483).

The activities of the Office of Production Management in 1941 with regard to coke byproducts centered on the available supply of and the requirements for the essential war products derived therefrom. The first control measure that became effective in 1941 concerning the supply and distribution of toluol was shown in the Federal Register (No. 171, vol. 6, title 32, pp. 4532–4533), issued and effective August 28, 1941; it related to conservation of supplies and directed distribution. Amendment 1, shown December 31, 1941, in the Federal Register (No. 253, vol. 6, title 32, p. 6853) placed further restrictions on uses, allocated supply, and extended the order indefinitely.

Phenol was another byproduct on which control measures were issued. Deliveries and acceptance were placed under the Director

of Priorities and appeared on September 3, 1941, in the Federal Register (No. 171, vol. 6, title 32, p. 4527), and the order was effective as of August 30, 1941. Amendment 1, issued and effective November 10, 1941, was shown in the Federal Register (No. 200, vol. 6, title 32, p. 5730).

Restrictions on the export of a large number of materials derived from the byproducts obtained from coke ovens became effective in 1941. The President of the United States, by proclamation, placed restrictions on the exportation of many coal-tar derivatives. The complete text of the proclamation appeared April 1, 1941, in the Federal Register (No. 63, vol. 6, title 32, p. 1703).

The necessity for controlling exports of important and essential materials derived from coke byproducts resulted in the issuance of Export-Control Schedules 1 and 2 by the Director of Export Control. Schedule 1, issued March 15, 1941, and effective April 15, 1941, was printed in the March 21, 1941, issue of the Federal Register (No. 56, vol. 6, title 32, ch. 8, p. 1540). Schedule 2, issued April 1, 1941, effective April 15, 1941, appeared in the April 8, 1941, issue of the Federal Register (No. 68, vol. 6, title 32, p. 1815).

TABLE 1.—*Salient statistics of the coke industry in 1941*

	Byproduct	Beehive	Total
Coke produced—			
At merchant plants:			
Quantity net tons	13,494,509		13,494,509
Value	$96,343,846		$96,343,846
At furnace plants:

Gas M cubic feet	10 81		10 81
Tar gallons	8 52		8.52
Ammonium sulfate or equivalent pounds	21 34		21.34
Value of byproducts sold			
Gas (surplus)	$85,040,609		$85,040,609
Tar.			
Sold	$18,386,170		$18,386,170
Used by producer	$14,708,855		$14,708,855
Ammonium sulfate or equivalent	$21,709,619		$21,709,619
Crude light oil and derivatives	$23,668,801		$23,668,801
Other byproducts [4]	$10,003,985		$10,003,985
Total value of coke and breeze produced and byproducts sold [5]	$499,525,703	$36,621,576	$536,147,279

[1] Increase in number of ovens in existence is due to number of old ovens previously reported abandoned that were rehabilitated in 1941.
[2] Figures cover January to September, inclusive
[3] Subject to revision. Includes net difference between imports and exports for first 9 months only.
[4] Includes naphthalene and tar derivatives.
[5] Includes value of tar used by producer.

TABLE 2.—*Statistical trends of the coke industry in the United States, 1923 and 1938–41*

	1923	1938	1939	1940	1941
Coke produced:					
Beehive net tons	19,379,870	837,412	1,444,328	3,057,825	6,704,156
Byproduct do	37,597,664	31,658,403	42,882,313	54,014,309	58,482,422
Total do	56,977,534	32,495,815	44,326,641	57,072,134	65,186,578
Percent of total from byproduct ovens	66.0	97.4	96.7	94.6	89.7
Stocks of producers, end of year, all coke net tons	[1] 1,221,737	3,676,554	2,602,099	1,956,442	1,758,086
Exports, all coke do	1,237,342	486,571	589,925	804,095	[2] 525,223
Imports, all coke [3] do	85,002	135,240	141,911	112,550	[2] 241,690
Consumption, calculated, all coke do	55,173,457	31,063,217	44,953,082	57,026,246	[4] 65,101,401
Disposal of coke, all coke sold or used:					
Furnace coke net tons	47,774,408	19,070,186	31,498,557	42,483,624	50,454,325
Foundry coke do	3,600,719	1,215,780	1,682,200	2,089,962	2,846,459
Other industrial (including water gas) net tons	[5] 2,283,888	2,786,710	3,193,068	3,581,676	4,224,597
Domestic coke do	2,733,414	7,222,690	7,638,141	8,231,013	6,682,959
For all other purposes do	(5)	1,175,346	1,311,559	1,458,435	1,165,526
Ovens:					
Beehive, in existence, end of year	62,349	10,816	10,934	15,150	18,669
Byproduct, in existence, end of year	11,156	12,724	12,732	12,734	13,016
Byproduct under construction, end of year	629	146	....	492	181
Cost of coal charged, byproduct ovens, average per ton	$4.76	$3.92	$3.75	$3.68	$3.92
Prices of coke:					
Average spot price of Connellsville furnace coke, f. o. b. ovens	$5.33	$3.86	$4.09	$4.42	$5.92
Average realization on byproduct coke sold:					
Furnace coke (merchant sales)	$6.74	$4.41	$4.38	$4.55	$5.70
Foundry coke	$10.54	$8.39	$8.15	$8.67	$9.76
Other industrial (including water gas)	$9.06	$5.68	$5.64	$5.86	$6.68
Domestic	$9.05	$6.17	$5.90	$6.03	$6.96
Yield of byproducts per ton of coal charged:					
Tar gallons	8.1	9.27	9.06	8.79	8.52
Ammonium sulfate or equivalent pounds	21.2	23.36	22.33	22.00	21.34
Light oil gallons	2.7	2.99	2.99	2.93	(6)
Surplus gas sold or used M cubic feet	5.9	7.14	7.08	6.84	6.71
Average gross receipts for byproducts, per ton of coke produced:					
Tar sold and used	$0.51	$0.654	$0.622	$0.571	$0.566
Ammonia and its compounds	$0.84	$0.380	$0.341	$0.364	$0.371
Light oil and its derivatives (including naphthalene)	$0.51	$0.423	$0.414	$0.421	(6)
Surplus gas sold or used	$1.37	$1.907	$1.676	$1.507	$1.454
Total byproducts, including breeze	$3.48	$3.647	$3.315	$3.117	$3.130

[1] Furnace and foundry coke only.
[2] Figures cover January to September, inclusive.
[3] Before 1934, figures represent general imports; beginning with 1934, they represent imports for consumption only.
[4] Subject to revision. Includes net difference between imports and exports for first 9 months only.
[5] "For all other purposes" included under "Other industrial (including water gas)."
[6] Figures withheld in accordance with Government policy.

SCOPE OF REPORT

This report presents, by means of selected tables, the essential facts concerning the 1941 production of byproduct and beehive coke (tables 3 to 45), coke breeze (table 26), coke byproducts (tables 46 to 51), and city-gas company statistics (table 52). In addition to the customary annual data, the report embodies the result of a survey of coking coal, which shows the State and county of origin, the tonnage supplied by the principal counties, and the percentage of total State tonnages by seams. As a result of a survey covering 1941, statistics showing the consumption of foundry coke in the United States, by States and regions, appear in this chapter for the first time.

Coke is produced by a group of four different industries in the United States. Most of the output comes from byproduct and beehive ovens, but small quantities are also made by petroleum refineries, coal-gas retorts, and tar refineries. The coke manufactured by each of these industries, however, varies greatly in character, and the problems affecting each are separate and distinct.

About 1,648,800 tons of petroleum coke and 91,800 tons of coal-tar pitch coke were produced in 1941 compared with 1,526,600 and 90,906 tons, respectively, in 1940. The tonnage of coke produced in coal-gas retorts is relatively small, and the 1941 figure is not available at present.

Only coke made from byproduct and beehive ovens is suitable for blast-furnace and foundry uses. As the metallurgical industries consume the bulk of all coke produced, the trade is concerned chiefly with byproduct and beehive coke, and the statistics of this report are confined to these two types.

The standard unit of measurement in the coke industry is the short or net ton of 2,000 pounds, and unless otherwise specified that unit is employed throughout this report.

COKE AND COKE BREEZE

MONTHLY AND WEEKLY PRODUCTION

TABLE 3.—*Byproduct, beehive, and total coke produced in the United States, 1938–41, by months and average per day, in net tons*

PRODUCTION BY FURNACE AND NONFURNACE PLANTS

The terms "furnace" and "merchant" plants originated in the Connellsville beehive-coke trade, although in this report the distinction is applied to byproduct-coke plants only. Furnace plants are those affiliated with the iron and steel industry, with an output that does not ordinarily enter the open market. Merchant plants include some that are affiliated with local iron furnaces but produce more coke than the furnaces can consume and therefore depend on foundry, domestic, or other markets. The term also includes producers of coke who sell their entire output on the competitive market; the plants affiliated with alkali works; low-temperature carbonization plants; and, in addition, a number of plants that, although not public utilities, were constructed primarily to supply city gas and sell their coke for domestic, industrial, and metallurgical use.

Production of coke follows closely the trend of the iron and steel industry. In 1941, 45 furnace plants produced 44,987,913 tons of coke (77 percent), and 42 nonfurnace plants produced only 13,494,509 tons (23 percent) of the total, which was the same ratio as in 1940.

TABLE 7.—*Number and production of byproduct-coke plants connected with iron furnaces and of other byproduct plants in the United States, 1913, 1918, and 1939–41*

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Other plants	Furnace plants	Other plants	Furnace plants	Other plants
1913	20	16	9,277,832	3,436,868	73 0	27.0
1918	36	24	19,220,342	6,777,238	73.9	26.1
1939	45	39	31,811,807	11,070,506	74.2	25.8
1940	45	40	41,465,177	12,549,132	76 8	23.2
1941	45	42	44,987,913	13,494,509	76.9	23.1

TABLE 8.—*Monthly and average daily production of byproduct coke by plants associated with iron furnaces and by all other plants in the United States, 1939–41, in net tons*

PRODUCTION BY STATES AND DISTRICTS

All coke-producing States except Michigan increased their output in 1941. The total output of byproduct coke (exclusive of screenings and breeze) in 1941 was 8 percent greater than in 1940, and the output of beehive coke was 119 percent greater than in 1940.

As in previous years, Pennsylvania was the leading producing State, contributing 27 percent of the byproduct and 88 percent of the beehive output. The largest gains were reported by Minnesota with an increase of 31 percent, Illinois with 21 percent, Tennessee and Ohio each with 18 percent, Indiana with 16 percent, and Colorado with 15 percent over the 1940 output.

The rehabilitation and operation during 1941 of a large number of beehive ovens that had long been idle partly explained the increased beehive-coke production. Alabama manufactured beehive coke in 1941 for the first time in many years. All producing States shared the increase in beehive-coke output. Pennsylvania produced approximately 88 percent of the Nation's total; Virginia, West Virginia, Alabama, and Colorado together contributed 11 percent; and all other States furnished only 1 percent (table 9.)

NUMBER AND TYPE OF OVENS

On December 31, 1941, 13,016 byproduct-coke ovens—an all-time peak—were in existence. During the year, 443 new ovens were completed and put into operation, and 158 ovens were abandoned. The total number on December 31, 1941, represented the ovens in existence at the end of 1940 plus the difference in new ovens completed and old ones abandoned, taking into consideration changes due to replacement and reclassification (footnotes 2 and 3, table 13).

During the year the Office of Production Management approved a number of new byproduct-coke plants required to supply blast-furnace coke for the expansion program of iron production. At the end of 1941, 181 new byproduct ovens, with an estimated annual capacity of 1,017,319 tons, were under construction. In general, there was enough coke during the year to take care of industrial requirements.

Impelled by the growing need for furnace coke in 1941, many beehive ovens that had been abandoned for several years were rehabilitated and restored to active operation. The average number of ovens

in operation—8,895 in December 1940—rose to 9,473 in January 1941. The number was increased in February and March but dropped in April to 3,212, owing to labor difficulties. Thereafter the monthly average of active ovens increased steadily for the remainder of the year and reached a peak of 12,321 in December, exceeding the December 1940 figure by 39 percent.

[1] Includes Koppers-Becker type.
[2] Includes 46 Curran-Knowles, 8 Piette, and 3 Disco ovens.

CAPACITY OF BYPRODUCT PLANTS

The relationship of production to maximum capacity of byproduct-coke plants in 1941 is shown in table 16. The maximum capacity of a byproduct plant is calculated by estimating the minimum coking time at which the ovens in that plant can be operated efficiently to produce coke suitable for the use for which it is intended. The theoretical maximum capacity seldom is attained in actual operation for various practical reasons that are governed by operating, economic, or labor conditions at the plant.

The efficiency attained by byproduct-coke plant operators in 1941 was the highest ever recorded in this country; production amounted to 92 percent of the maximum capacity of the ovens.

The maximum daily capacity of the 87 byproduct-coke plants in existence December 31, 1941, was 171,404 tons compared with 170,467 tons for 89 plants at the end of 1940. The daily capacity of the 42 merchant plants was 41,928 tons and that of the 45 furnace plants 129,476 tons.

TABLE 16.—*Relationship of production to potential maximum capacity [1] at byproduct-coke plants in the United States, 1929 and 1938-41, by months, in percent*

[1] Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND COST OF COAL CHARGED

The quantity of coal used for making coke in 1941 totaled 93,138,153 tons; this amount was the highest on record and exceeded that used in 1940 by 11,752,377 tons or 14 percent. Byproduct ovens consumed 82,608,837 tons of coal, an increase of 6,026,057 tons (8 percent); and beehive ovens used 10,529,316 tons, or 5,726,320 tons more than in 1940. Coal charged into coke ovens represented 18 percent of the total estimated production of bituminous coal for the year.

The cost of coking coal rose sharply in 1941. The average cost of coal charged into byproduct ovens was \$3.92 compared with \$3.68 in 1940, an increase of \$0.24 per ton. It is of interest to note that, although the cost of coking coal throughout the Nation increased, the cost per ton of coal charged into byproduct ovens in Pennsylvania declined from \$2.84 in 1940 to \$2.69 in 1941.

The cost per ton of coal charged into byproduct ovens is determined chiefly by the location of the coke plant with relation to its sources of coal—in other words by the cost of transportation. West Virginia, with an average cost of \$2.63 per ton, was the lowest in the country; Minnesota, with a cost of \$5.19 per ton, was the highest.

The average cost per ton of coal charged into beehive ovens was \$2.33 compared with \$3.92 for byproduct ovens, as beehive ovens generally are situated near the sources of coal. The yield of coke per ton of coal charged into beehive ovens is less than the yield from byproduct ovens. However, the lower cost per ton of coal charged into beehive ovens explains the lower cost of the quantity of coal required to produce 1 ton of coke—\$3.66 for beehive ovens compared with \$5.53 for byproduct ovens.

The cost per ton of the coal used in beehive ovens in 1941 ranged from \$1.94 in Virginia to \$3.64 in two Western States—Colorado and Utah.

PREPARATION AND SOURCE OF COAL

The cleaning of coal to reduce its ash and sulfur content is of increasing importance to the coke industry in the United States. Many inferior coals require only washing to produce a good-quality metallurgical or domestic coke in coke ovens. Coke made from high-ash and high-sulfur coals causes definite economic losses in the blast furnace. If the coal charged into ovens is high in ash content, the coke produced has an even higher ash content, which is not desirable in industrial or domestic coke.

Of the coal consumed in byproduct ovens during 1941, all of that used in Colorado and Tennessee, 90 percent of that used in Alabama, and more than a third of that used in Pennsylvania was washed (table 20). Both pneumatic cleaning and wet washing methods are employed to prepare coal for use in coke ovens, depending on local conditions. Some coal is washed by producers at mines and some by coke-plant operators at plants. Of the total coal charged into byproduct ovens during 1941, 20,671,576 tons (25 percent) were washed. In the beehive-coke industry only 1,441,757 tons (14 percent of the total) were washed.

TABLE 20.—*Washed and unwashed coal used in manufacturing coke in the United States in 1941, by States in which used, in net tons*

State	Washed	Unwashed	Total

Beehive plants:			
Alabama	154,740	2,200	156,940
Colorado and Utah	124,198	20,106	144,304
Kentucky and Tennessee	66,035	3,424	69,459
Pennsylvania	1,096,784	8,099,579	9,196,363
Virginia		540,759	540,759
West Virginia		421,491	421,491
	1,441,757	9,087,559	10,529,316

Four States furnished most of the coal consumed in byproduct-coke plants. Pennsylvania, with 34,670,699 tons, led the Nation, followed by West Virginia, with 29,425,684 tons; Kentucky, with 9,271,279 tons; and Alabama, with 6 462,661 tons. Together these States supplied 96 percent of all coal used in byproduct ovens in 1941.

TABLE 21.—*Coal purchased for manufacture of byproduct coke in the United States in 1941, by fields of origin, in net tons*

[Based upon detailed reports from each coke plant. Difference between these totals and those shown in tables 1, 10, 17, etc., is due to change in stock, loss of weight in handling, and the fact that these represent purchases during the year rather than actual consumption]

State and district where coal was produced	Total purchased	States where coal was consumed—in order of importance
Alabama	6,462,661	Alabama.

The examination and development of new sources of coking coal are important because of the irregular and limited distribution of high-grade coals of established coking quality. Owing to the rapid rate at which the reserves of such coals are being depleted, the blending of various types of coal is a conservational as well as an efficiency measure. The custom of mixing a variety of coking coals before charging into the ovens is primarily to produce economically coke of a quality satisfactory for the use for which it is intended. Some coals with many satisfactory coking qualities expand when coked, and their use alone would cause difficulty in discharging the coke from the oven and might even injure the byproduct-oven walls. For this reason, it is customary to mix such coals with others having a lower coefficient of expansion. This practice also permits the use of coals that have good coking qualities but have objectionable impurities, such as high content of ash, sulfur, and phosphorus. Such coals should not be used as a 100-percent charge in the ovens. Coal mixtures are commonly used at byproduct-coke plants, and this practice has resulted not only in the production of superior coke but also in the extensive utilization of coals, which, in unmixed condition, would not be suitable for coke manufacture.

Classification of all coal purchased for coking in byproduct ovens in 1941 from the data supplied by the operators showed that 53,875,666 tons (65 percent) were high-volatile coal containing over 32 percent volatile matter; 10,880,601 tons (13 percent), medium-volatile coal containing 23 to 31 percent volatile matter; and 18,431,035 tons (22 percent), low-volatile coal or coal containing 14 to 22 percent volatile matter.

SOURCES OF COKING COALS [1]

The increased emphasis placed upon the coke industry by the war program has created widespread interest in coke production. An adequate supply of suitable coal is the prime requisite of the coke industry, and the urgent demand for metallurgical coke by the iron

[1] Prepared by J. R. Bradley, Coal Economics Division, Bureau of Mines.

and steel industry has greatly augmented the need for coking coal. The following table shows the sources of production of coking coals by States, counties, and beds. Four Eastern States (Pennsylvania, West Virginia, Kentucky, and Alabama) mined 93 percent of the output, and only a small percentage of coking coal is mined west of the Mississippi River. Production in 1940 by mines that shipped coal to coke plants in 1941 totaled 171,440,000 tons, of which Pennsylvania's Connellsville region contributed 25 percent, Pennsylvania outside of the Connellsville region 13 percent, West Virginia 40 percent, Kentucky 10 percent, and Alabama 5 percent. The principal producing counties in West Virginia were McDowell, Raleigh, Fayette, and Marion, which supplied 35, 20, 12, and 11 percent, respectively. The Pocahontas bed produced 48 percent of the State total, Pittsburgh bed 11 percent, Eagle bed 8 percent, and all other beds 33 percent. In Pennsylvania the Connellsville region produced 42,473,000 tons, of which that supplied by Fayette County represented 47 percent, Washington County 24 percent, and Westmoreland and Greene Counties about 11 percent each; of the Connelsville total the Pittsburgh bed supplied 89 percent and the Freeport bed 8 percent. Pennsylvania outside of the Connellsville region produced 21,741,000 tons, of which Allegheny County supplied 42 percent and Cambria County 41 percent; the principal beds from which the coal was produced were the Kittanning (33 percent), Freeport (29 percent), and Pittsburgh (17 percent).

Of the 17,371,000 tons of coal produced in Kentucky, Harlan County supplied 49 percent, and Floyd, Letcher, and Pike Counties 18, 16, and 13 percent, respectively. The principal beds mined were the Elkhorn, with 35 percent of the State total, Kellioka 23 percent, and Harlan 19 percent. In 1940 Alabama produced 9,283,000 tons, of which Jefferson County supplied 88 percent. The principal beds mined were the Pratt, which supplied 44 percent, and the Mary Lee, 42 percent.

[1] Yield computed by dividing production of breeze by coal charged at plants actually recovering.
[2] Included under "Undistributed."
[3] As reported; quantity produced but not used was undoubtedly greater. See Mineral Resources of the United States, 1922, part 2, pp. 726-727.

CONSUMPTION OF COKE

Records of the consumption of coke are important because of the light that they throw on the trend of demand and hence on the prospects for future expansion of the industry. The calculated consumption of coke in 1941, making allowance for imports and exports from January through September only and changes in producers' stocks, was 65,101,401 tons. In comparison with 1940, the year showed an increase of 8,075,155 tons.

The principal use of coke in 1941 was in blast furnaces, where it is one of the basic materials employed for smelting iron ore. Unprecedented activity in the iron and steel industry in 1941 was due to the demand for steel to build war equipment. According to figures compiled by the American Iron and Steel Institute, 49,469,972 tons of coke (approximately 76 percent of the total coke consumption) went into blast furnaces for the manufacture of pig iron and ferro-alloys. The remainder—24 percent—was used in foundries, in smelting the nonferrous metals, in the manufacture of water gas, in miscellaneous other industrial uses, and in domestic heating.

Improvements in blast-furnace fuel efficiency and in the quality of the coke have resulted in a decline in coke requirements per net ton of pig iron produced (table 28). In 1913 blast furnaces required 2,172.6 pounds of coke per ton of pig iron; this has decreased until an all-time low of 1,767.8 pounds of coke per ton of pig iron and ferro-alloys was established in 1941.

TABLE 27.—*Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, and 1938–41, in net tons*

Year	Total production	Imports	Exports	Net change in stocks	Indicated United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways

[1] Production plus imports minus exports, plus or minus decrease or increase, respectively, of net changes in stocks.
[2] From Report of American Iron and Steel Institute Figures include coke consumed in manufacture of ferro-alloys.
[3] Data not available.
[4] Figures cover January to September, inclusive.
[5] Subject to revision. Includes net difference between imports and exports for first 9 months only.

TABLE 28.—*Coke and coking coal consumed per net ton of pig iron made in the United States, 1913, 1918, and 1938–41*

Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)	Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)
1913	2,172.6	66 9	3,247 5	1939	1,778 0	69 8	2,547.3
1918	2,120.7	66 4	3,193.8	1940	1,781.2	70 1	2,540.9
1938	1,801 0	69.7	2,583.9	1941	1,767.8	70.0	2,525.4

[1] From Report of American Iron and Steel Institute; consumption per ton of pig iron only, excluding furnaces making ferro-alloys, was 2,172.6 in 1913, 2,120.7 in 1918, 1,774.6 in 1938, 1,760.0 in 1939, 1,756.9 in 1940, and 1,745.2 in 1941.

FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

The trade terms "furnace coke" and "foundry coke" refer to the size and grade, as well as to the use for which the coke may be intended. The requirements for good furnace coke and good foundry coke differ in some respects. Uniformity is vital to successful and economical blast-furnace operation. Furnace coke preferably should be uniform in size and in ash, sulfur, and phosphorus content; it usually is run-of-oven minus the small coke and breeze.

Foundry coke is somewhat different from furnace, as its only function in the cupola is to furnish heat to melt the iron, whereas in the blast furnace the function is twofold—to supply carbon monoxide for reduction and heat to melt the iron. The requirements of good foundry coke are minimum reactivity with carbon dioxide gas, larger size than blast-furnace coke (over 2½ to 3 inches), hardness and strength sufficient to prevent excessive degradation by impact of the massive iron charged into the cupola shaft, and relative freedom from impurities.

The most important characteristics of domestic coke are the ash content, fusing temperature of the ash, and density. Domestic coke may be screened from furnace or foundry coke, or it can be obtained by crushing the larger sizes. Special purposes may require other sizes and grades of coke. Not all furnace coke is used in blast furnaces or all foundry coke in foundries; and either grade may be purchased by other classes of consumers.

Coke as a domestic fuel is used chiefly in regions where there is a surplus of metallurgical coke or where there is a large production of city gas and corresponding large quantities of coke that must find a market. In the latter case, gas is the primary product and coke a byproduct in contrast to furnace and merchant plants, where coke is the primary product and gas a byproduct. Most of the coking plants are equipped to screen and size coke for domestic use.

In 1941 the sales of all kinds of coke except that for domestic use increased substantially. The demand for metallurgical fuel caused diversion of coke from domestic use to the metallurgical industry. Byproduct coke sold for furnace use, including coke sold to financially affiliated corporations, totaled 6,215,601 tons—21 percent more than in 1940. Foundries purchased 2,494,393 tons, a 34-percent increase over 1940. The increase in coke for metallurgical use resulted in a 19-percent decrease from 1940 in sales of domestic coke. The sales of byproduct coke for domestic use totaled 6,596,969 tons compared with 8,131,947 tons in 1940. Sales of industrial coke in 1941, including that used for the manufacture of water gas, amounted to 1,844,126 tons, an increase of 5 percent.

Sales of beehive coke in 1941 increased in proportion to the large increase in production. Coke sold by producers for blast-furnace use amounted to 4,805,099 tons compared with 1,799,292 tons in 1940, an increase of 167 percent. Most of the beehive coke is used in blast furnaces. Sales for foundry use increased 52 percent and those for industrial and other uses (including water gas) 46 percent. Beehive coke sold for domestic use declined from 99,066 tons in 1940 to 85,990 tons in 1941, or 13 percent.

CONSUMPTION OF FOUNDRY COKE IN 1941

The important position of the foundry industry in the economic picture of the country is understood when it is pointed out that every one of the 3,000 foundries had to buy metals (mainly pig iron and ferrous scrap), coke, and sand. There resulted a large freight movement which utilized probably every railroad and waterway in the Nation to transport raw materials going into the foundry and castings coming out.

Coke is a basic fuel material in the cupolas and furnaces of the foundries, and coke must have suitable characteristics to meet the fuel requirements.

The American Society for Testing Materials has adopted the following specification limits [2] for the composition of foundry coke:

	Percentage in dried sample
Volatile matter	(not over) 2.0 percent
Fixed carbon	(not over) 86.0 percent
Ash	(not over) 12.0 percent
Sulfur	(not over) 1.0 percent

[2] American Society for Testing Materials, Specification D-17-16 for Foundry Coke: A. S. T. M. Standards for 1939, part III, Nonmetallic Materials, pp. 59-61.

Foundry coke must be of the highest quality; it therefore commands a premium over other grades of coke. The chemical and physical characteristics of coal-tar-pitch coke and petroleum coke make them unsuitable for foundry use. The only coke suitable for such use is that produced in byproduct or beehive ovens.

The national consumption of foundry coke in 1941 totaled 2,679,581 tons.

Widespread use of foundry coke is indicated by the fact that all States except Wyoming reported coke consumed for this purpose in 1941. Figures showing the consumption of foundry coke, by States, in 1941 reveal that Michigan consumed the largest amount—423,167 net tons. Pennsylvania was second with 321, 892 tons, Ohio third with 321,693 tons, and Illinois fourth with 225,253 tons. These four States consumed a total of 1,292,005 tons, or 48 percent of the entire consumption of the country. Substantial tonnages of foundry coke, aggregating 737,206 tons, or about 28 percent of the total, were consumed in Alabama, New York, Indiana, New Jersey, and Wisconsin.

The comparative consumption of foundry coke, by regions, is shown in table 31. From this table it will be noted that the Midwest region was far ahead in foundry-coke consumption during the year. The seven States composing this region used 1,312,423 tons, or 49 percent of the total of 2,679,581 tons. The Central Atlantic region was next, with a consumption of 715,576 tons, representing 27 percent of the total. All other regions consumed the remainder of the tonnage, or about 24 percent.

According to the figures submitted by the operators, stocks of foundry coke amounted to 302,795 tons at the end of the year, and they estimated that coke requirements for foundry purposes in 1942 would reach 2,877,134 tons.

STOCKS OF COKE AND COKING COAL

Stocks of coke are governed by the demand from industry. The abnormal demand for coke in 1941 resulted in a decrease in stocks held by the producers at the end of 1941. Total stocks of coke at the end of the year were 198,356 tons less than at the beginning. Byproduct coke declined 11 percent below the stocks at the beginning of the year and totaled 1,709,391 tons (table 33). The stocks of coke held at beehive plants, which are relatively small, increased during the year to 48,695 tons compared with 43,308 tons at the end of 1940.

The stocks of bituminous coal at byproduct ovens in 1941 closely followed the trend of monthly coke production. They were largest at the end of February and smallest at the end of May. Beginning

with June, stocks increased each month (except November) until the end of December, when they amounted to 8,901,462 tons.

TABLE 32.—*Stocks of furnace, foundry, and domestic coke and of breeze in the United States on January 1, 1942, by States, in net tons*

VALUE AND PRICE

In previous years, reference has been made in the Coke chapters to the various accounting methods used by coke operators affiliated with iron and steel plants, by which the coke sometimes is charged to the furnace department at cost and sometimes includes a percentage of profit at the current market price. In the open market, however, price cutting, long-term contracts, and other factors materially affect the prices at which coke-plant operators actually dispose of coke. According to sales data furnished by the operators, average receipts per ton for byproduct coke sold rose as follows: Furnace coke, $0.61; foundry, $1.09; domestic, $0.93; and other industrial, $0.82. Average receipts from the sales of beehive coke in 1941 increased over 1940 as follows: Furnace coke, $1.17; foundry coke, $1.38; domestic coke, $1.05; and other industrial coke, $1.50.

Trade-journal quotations published in 1941 showed that the price of byproduct foundry coke increased in all markets. The increases ranged from $0.96 in New England to $0.33 at St. Louis, Mo. Connellsville prices for beehive coke, usually the basis for the beehive-coke industry, rose $1.50 per ton for furnace coke and $1.14 per ton for foundry coke.

Grand total		6,457,090	6,457,090	100.0

[1] Coke delivered by trucks to consumers in all States that produced beehive coke.

DISTRIBUTION OF BYPRODUCT AND BEEHIVE COKE IN 1941

Coke shipped by producers, or used by them, is shown by States and regions of destination and by uses in this analysis. The tonnage shipped to each destination represents approximately the coke consumed therein; and, for practical purposes, the terms "distribution" and "consumption" are interchangeable in this connection. However, the total coke shipped and used by producers shown in this separate study of coke distribution differs slightly from the total "calculated" consumption of coke in 1941, shown in the preceding section on Consumption of Coke.

The national consumption of byproduct and beehive coke, not including imports, in 1941, totaled 64,876,457 tons, a 13-percent increase over the 1940 total of 57,170,633 tons. Pennsylvania led in total tonnage consumed, with 17,867,567 tons, followed by Ohio, New York, Indiana, and Illinois in the order named.

As activity in the coke industry follows closely that in the iron and steel industry, it is interesting to note that the increase in blast-furnace coke consumption paralleled the increase in total coke production in 1941. Of the 64,876,457 tons of coke consumed in 1941, 50,331,675 tons went into blast furnaces. The trend of coke consumption from domestic to metallurgical use can be seen from the decrease in domestic tonnage from 1940. In 1941, 6,660,847 tons of domestic coke were consumed compared with 7,974,308 tons in 1940.

Every State in the Union, as well as the District of Columbia, consumed foundry coke during 1941. The total, amounting to 2,787,527 tons, was 35 percent greater than in 1940. Coke used for making producer gas and water gas and for other industrial uses increased

8 percent, with a tonnage of 5,096,408 tons compared with 4,732,890 tons in 1940.

The total consumption of breeze in the United States in 1941 amounted to 4,651,982 net tons, an increase of 582,289 tons over the 1940 figure.

The consumption by uses in 1941, by geographical regions, is shown in table 41. When compared with 1940, consumption increased in seven of the nine regions and decreased in two of them. The largest increase was in the Ohio region, which gained 25 percent over the 1940 figure, followed by the Illinois-Indiana region, with a gain of 21 percent. The Missouri Valley region had the greatest decrease in coke requirements, with a 16-percent decline from the 1940 total, and Michigan declined 10 percent.

Table 42 shows where the coke produced in each State was consumed. Although Alabama shipped coke into the greatest number of States in 1941, the tonnage was relatively small, as 92 percent of the coke produced in the State was consumed there. Pennsylvania shipped into 27 States, leading the Nation in total tonnage shipped outside the State with 3,902,258 tons. Indiana, which was second highest, shipped 1,935,028 net tons in 1941.

TABLE 40.—*Summary of byproduct and beehive coke and breeze consumed in each State in 1941, in net tons*

[Based upon reports from all United States producers showing destination of coke used by producer or sold in 1941. Does not include imported coke, which totaled 241,690 net tons from January to September, inclusive]

EXPORTS AND IMPORTS [3]

The export movement of coke in 1941 was small compared with the total tonnage produced. From January through September 1941—the only period of the year for which foreign trade figures can be pub-

[3] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

lished—the exports of coke from the United States totaled 525,223 net tons valued at $4,021,357.

Imports of coke constitute a small part of this country's requirements in normal times. However, the need for coke by the metallurgical industry in 1941 resulted in more than doubling the 1940 imports during the first 9 months. The imports of coke are a factor in the home market only in certain localities. The entire tonnage of coke received by the United States from January through September 1941 was furnished by the United Kingdom and Canada, the largest tonnages coming through ports in Maryland, Massachusetts, and Buffalo.

WORLD PRODUCTION

In consequence of the European War of 1939 and 1940, which expanded into a world war involving the United States in 1941, the number of countries releasing data on the production of coke decreased steadily. The statistics submitted in table 45 are incomplete, as data from the principal producing countries other than the United States are not available; however, Canada, as well as the United States, surpassed the peak year of 1929 in the production of coke.

[1] Gas-house coke is not included.
[2] In addition to countries listed, coke is produced in Chosen and Japan, but data of production are not available.
[3] Data not available.
[4] January to August, inclusive.
[5] Excluding Sudetenland since October.
[6] In Great Britain the production of gas-house coke (including breeze), not included above, is especially important and was 13,049,139 tons in 1938.
[7] Figures for 1929 represent "hard" and "soft" coke made at collieries only—73,616 tons of "hard" coke and 769,888 tons of "soft" coke. Data for other years shown represent total "hard" coke manufactured. In addition, the following quantities of "soft" coke were made at collieries: 1938, 921,479 tons; 1939, data not available.
[8] Incomplete figure (from coke plants of only 2 mines).
[9] January to June, inclusive.
[10] Exclusive of Mexico.

COKE-OVEN BYPRODUCTS

SUMMARY OF BYPRODUCTS

The acute demand for toluol, benzol, phenol, naphthalene, and other valuable byproducts recovered from the carbonization of coal has definitely enhanced the importance of these commodities in the national economy. Basic materials derived from the distillation of coal in byproduct ovens are not only vital to the war program, but they are also an important source of revenue to plant operators and a means of reducing to a minimum the net cost of converting coal to coke. Approximately one-fifth of the annual production of bituminous coal in the United States is consumed in byproduct ovens, a tonnage exceeded only by that consumed by railway locomotives. The increased production of coke for metallurgical purposes has augmented the production of all primary byproducts, the demand for which, fortunately, has also increased. In the past, however, conditions governing the demand for all the byproducts of the coking process have not always been favorable, and their economic distribution has been a problem to producers.

Because of the complex nature of many coke byproducts, which require special technical processes, equipment, and operating technique for their economical production, most byproduct coke plants do not have the necessary facilities for complete processing of the byproducts and are concerned only with the major byproducts—gas, tar, light oil and its derivatives, and ammonia (table 46).

The total output of coke byproducts reached an all-time high in 1941, although the total value was slightly less than in 1929 due to the lower selling prices of ammonium sulfate and light-oil derivatives. In 1941 the total sales value of all coke byproducts exceeded that of 1940 by $13,727,307 and totaled $158,809,184. This figure represented 50 percent of the value of the coke produced in byproduct ovens. From these figures it can readily be seen why the byproduct ovens have largely replaced the beehive ovens in the coke industry (see also fig. 2). Of interest is the increased output and value of distillate creosote oil. Production in 1941 totaled 38,283,662 gallons compared with 27,150,656 gallons in 1940, an increase of 41 percent. Sales of distillate creosote oil rose from 62 percent of the total production in 1940 to 102 percent in 1941, thereby increasing the value of sales from $1,832,348 to $4,583,327. Tar-acid oil, another tar derivative, is also worthy of mention. The major use of creosote is in wood preservation, and tar-acid oils are used in the manufacture of plastics, disinfectants, and dips and for ore flotation.

Gas.—As gas is now the most valuable coke-oven byproduct, it is given special attention in the following tables. Tables 47 and 48 present details of the quantities recovered, used, and sold in 1941, by States. In addition to supplying the fuel needs of the coke ovens, a surplus of 554,126,449 M cubic feet (62 percent of the total of 892,819,811 M cubic feet of gas produced) was sold or used for industrial purposes and for distribution through city mains. Receipts from gas sold by byproduct-coke plants in 1941 totaled $85,040,609, an advance of $3,638,562 over the 1940 figure of $81,402,047. The average unit price for 1941, as reported by the operators, was $0.153 per M cubic feet, a decrease of $0.002 per M cubic feet from the 1940 price of $0.155. The sale of surplus gas produced approximately 53 percent of the total revenue derived from all the byproducts in 1941.

Tar.—Tar, a very important coke byproduct, is the basic material for hundreds of chemical compounds. The crude tar recovered requires special equipment for complete processing, and many plants that are not equipped to process the tar sell their crude tar to refineries. Statistics on the topping of coal tar were collected by the Bureau of Mines for the first time in 1940, when 94,890,278 gallons were topped. The tar topped in 1941 totaled 103,653,501 gallons. Topping is practiced to obtain from tar at byproduct plants, where complete refining equipment is not available, certain constituents, including light oil and tar acid fractions, and in some plants, even higher fractions. Growing recognition of the importance of creosote oil, a derivative of coal tar, is indicated by the increase in its production and value in 1941. The wasteful practice of burning tar for fuel is steadily being discontinued, and the recovery of its valuable constituents is being practiced by more plants each year. Statistics on the production and sales of coke-oven tar during 1941 are shown in table 49.

Ammonia.—Another major byproduct of the coke ovens is ammonia. It is used in the manufacture of nitric acid, explosives, and commer-

cial fertilizers. The relatively low cost of making ammonium sulfate from the ammonia recovered in the carbonization of coal and the large demand for sulfate to be used in commercial fertilizers accounts for the fact that the bulk of the ammonia recovered from byproduct-coke ovens goes into ammonium sulfate. The value of ammonia in relation to the total value of all byproducts has declined considerably from 1913, when 45 percent of the value of all byproducts was furnished by ammonia compared with 14 percent in 1941. This can be attributed to the development in recent years of more economical methods for the manufacture of ammonia. The 1941 production of ammonium sulfate totaled 1,490,395,760 pounds and exceeded the previous all-time high of 1,488,314,447 pounds produced in 1929. The value of ammonium sulfate, $0.013 per pound, exceeded the 1940 figure by $0.001 (table 50).

Light oil and its derivatives.—The derivatives of light oil are in acute demand by the war industries. Benzol is one of the major derivatives of light oil and is essential to the manufacture of so-called synthetic phenol. This in turn is required for the production of picric acid and is urgently needed as a high explosive and chemical warfare intermediate. Phenol is also essential in the manufacture of the phenol formaldehyde plastics used in our metal-substitution program and in the manufacture of nylon, a silk replacement. Benzol has wide application as a solvent and also as an ingredient in fuels for internal-combustion engines. Toluol is a basis of high explosive production when nitrated to di- and tri-nitrotoluol (TNT). The toluol used for making explosives is of very high quality and commands better prices than the industrial-grade toluol used as a commercial solvent. Xylol has many minor current demands as a relatively high boiling solvent and in many ways is being used to replace toluol. There was a substantial increase in the output of light oil and its derivatives in 1941 when compared with 1940. Receipts from the sales of light oil and its derivatives totaled $23,668,801 in 1941, an increase of $2,164,672 over the 1940 figure.

Naphthalene.—Naphthalene, another important byproduct derived from tar and light oil, is used in the manufacture of explosives, resins, and plasticizers. In addition, considerable quantities are used as a moth repellant for clothing. According to preliminary figures the output of naphthalene in 1941 totaled 83,810,422 pounds.

[1] Includes products of tar distillation conducted by coke-oven operators under same corporate name, except, however, phenol and other tar acids produced at Clairton, Pa.
[2] Includes gas wasted and gas used for heating ovens.
[3] Final figures withheld in accordance with Government policy. Preliminary production figures of benzol and toluol were 145,448,733 and 29,056,551 gallons, respectively.
[4] Preliminary figure.
[5] Ammonium thiocyanate, cyanogen, phenol, sodium phenolate, sodium prussiate, spent soda solution, sulfur, vented vapors, orthoxylene, dicycloentadiene, sal ammoniac, alpha picolene, and a small amount of miscellaneous products.
[6] Exclusive of value of breeze production, which was $9,530,433 in 1941.

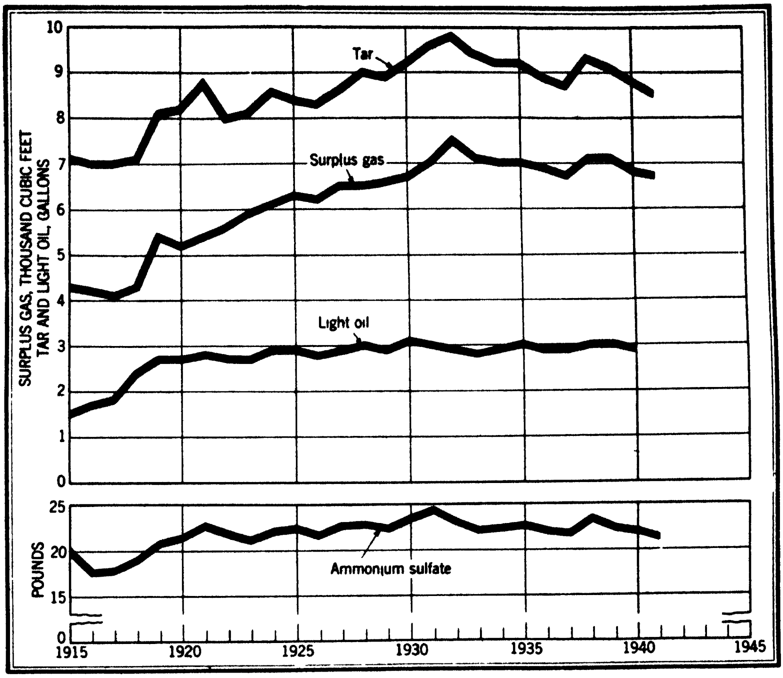

FIGURE 2.—Average yield of principal byproducts per net ton of coal carbonized in byproduct-coke ovens, 1915–41. Figures for light oil represent average at plants recovering light oil.

BYPRODUCT-COKE OVENS OWNED BY CITY-GAS COMPANIES (PUBLIC UTILITY PLANTS)

In city-gas plants more emphasis is placed upon the production of gas of proper analysis than upon the grade of coke made. However, with regard to the supply and demand for coke and byproducts, these installations belong to the byproduct-coke industry and are therefore included in the statistics supplied by the Bureau of Mines. The adaptability of byproduct ovens to the needs of city-gas manufacture has led a number of gas companies to install batteries of byproduct ovens to supplement or even replace coal or water-gas plants.

Sixteen byproduct plants owned by city-gas companies manufactured 3,403,374 tons of coke in 1941. This was an increase of 46,971 tons over 1940 and represented 6 percent of the byproduct-coke production of the country.

The following table presents salient statistics for 1940 and 1941 of the city-gas byproduct-coke plants in relation to the industry as a whole.

FUEL BRIQUETS AND PACKAGED FUEL[1]

By G. S. Goodman

SUMMARY OUTLINE

The effect of the war was felt in both the fuel-briquet and packaged-fuel industries in 1941 through increased costs of raw materials and labor but far more seriously in the packaged-fuel industry where shortage of paper caused cancelation of a number of contracts for installations of machinery at new plants and resulted in the shut-down of 22 plants—some permanently. One manufacturer of briquetting machinery reported diversion of his business to the construction of special machines for briquetting ores and metal wastes for war work.

The world-wide reduction and dislocation of normal trade resulting from the war brought inquiries from Argentina for technical advice regarding the possibility of briquetting huge, unexportable surpluses of corn and corn husks to augment its reduced imports of coal and oil; and an American briquetting machine was shipped to the Institute of Technology at Rio de Janeiro, Brazil, to be tested in briquetting coal and other fuel materials—also in an effort to meet urgent fuel needs.

The fuel industry is keeping close watch on national developments in order to be prepared to meet all possible fuel requirements. Although the fuel-briquet industry in the past few years has been expanding gradually upon a sound basis in well-established markets, potential operators might well recall that during the World War of 1914–18 scarcity of other fuels created an unprecedented demand for briquets for domestic use, but that the Armistice found this country stocked with coal far exceeding its peacetime requirements. When munitions plants were closed, industrial demand receded, flooding the domestic market with coal for household use and reducing the market for fuel briquets more than one-third in 1919. Whether the coal trade will return to its former channels of consumption after the present war or will establish new foreign markets for United States production cannot be forecast at this time.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.
Data on employment and the principal expenses in the manufacture of fuel briquets may be obtained from the Bureau of the Census, which collects and publishes such data in alternate years; 1939 is the latest year for which such data have been collected.
Briquets made from charcoal, wood wastes, and fruit pits are not included in the Bureau of Mines review.

Fuel briquets produced in the United States reached an all-time high of 1,298,606 net tons in 1941—a 24-percent increase over 1940; the output of packaged fuel (considered separately in this report) amounted to 269,844 net tons—a 5-percent decrease from 1940. The combined output totaled 1,568,450 tons, valued at $10,473,396.

Records have been collected on the production of fuel briquets since 1907, when production was but 66,524 tons, with 11 plants in operation. Data on packaged fuel collected since 1935 show, for 1941, the first decline in production since its phenomenal record of growth.

Technologic developments.—Notwithstanding the war, the briquetting and packaged-fuel industries continued their research work in 1941 although a number of projects in the laboratory stage have been laid aside in favor of military work.

In the fall of 1941, V. F. Parry of the Technologic Branch, Bureau of Mines, Golden, Colo., began a technologic and engineering study of the fuel-briquetting and packaged-fuel industries, visiting about 35 operations. When additional plants are inspected the results of the study will be published.

Construction of the commercial-scale briquetting press designed by R. J. Piersol[2] at the Illinois State Geological Survey was completed in 1941, but final demonstrations on briquetting various Illinois coals have been postponed until sometime in 1942, owing to delays in delivery of necessary equipment because of war priorities.

In 1940 Dr. Piersol reported that deduster dust and sludges from many Illinois coals contain large quantities of fusain, which is relatively smokeless. When these dusts are briquetted the resulting fuel briquet is less smoky than average Illinois coal; if enough fusain is present, the briquets will meet the restrictions set up by the St. Louis smoke ordinance. During 1941 a major Illinois coal operator started large-scale production of briquets made of dust and screenings from mines and from a deduster plant in Franklin County, using a binder.

Komarek-Greaves & Co.,[3] of Chicago, Ill., is reported to be experimenting in the manufacture of briquets from low-volatile coal without binder, using a roll press that develops 30,000 to 40,000 pounds pressure per square inch. Although briquets made by this method are not as strong as briquets made with binder, they will stand handling and if bagged should make a satisfactory fuel.

A new, low-priced briquetting machine (with a capacity of about 70 tons per 24-hour day) to be used at docks, yards, and small coal mines for making pillow-shaped briquets to be sold in bulk was introduced in 1941 by the manufacturers of Eberling packaged-fuel machines. The product is said to be suitable for local truck delivery and storage in coal bins not exposed to the weather. The Smokeless Coal-Blox Co. plant in St. Louis[4] has been equipped with a machine of this type (as well as with several units of the Glenn-Smith type, making cubes).

The new packaged-fuel process and machinery developed by the Viking Machinery Co., Jackson, Mich., are discussed under Processes in the Packaged Fuel section of this report.

A new plant—Coal Logs Co., Inc., of Salt Lake City—to process Utah coals without binder and reported to produce a 100-percent smokeless fuel is scheduled for operation in April 1942.[5] Test work during the past 2 years is said to have proved successful.

FUEL BRIQUETS

The salient statistics of the fuel-briquetting industry from 1937 to 1941 are summarized in the following table (data on imports and exports during the last quarter of 1941 are not available for publication). Detailed data for earlier years, beginning with 1907, are to

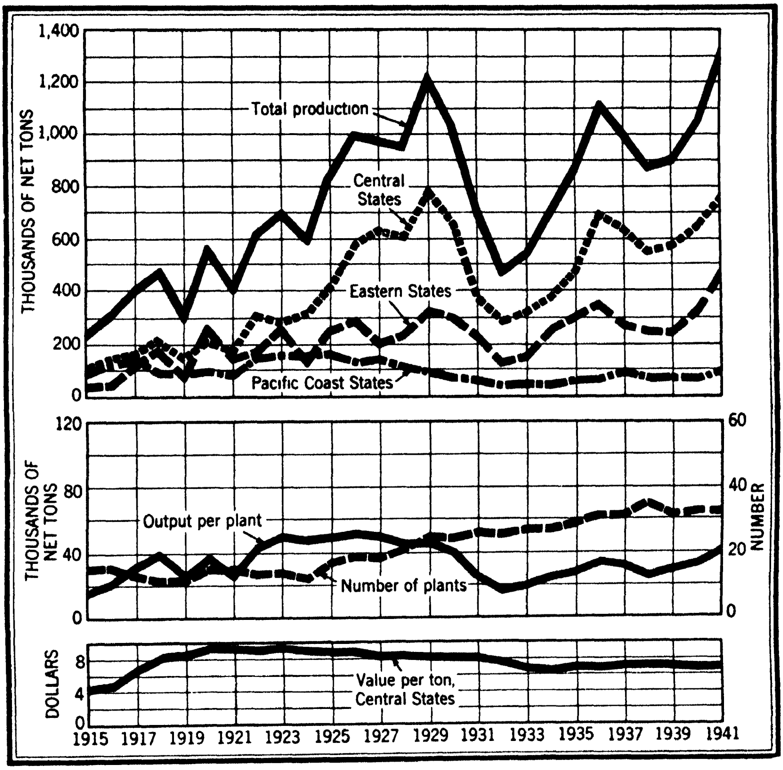

FIGURE 1.—Production of fuel briquets, number of plants in operation, and average value per ton, f. o. b. plant (Central States), 1915–41.

be found in annual issues of Mineral Resources (part II) and Minerals Yearbook, which include chapters on briquetting. Production and value from 1915 to 1941, inclusive, are presented graphically in figure 1 of this report.

[1] Exports reported separately by Department of Commerce beginning with 1937.
[2] Production plus imports minus exports.
[3] Imports for January to September, inclusive, totaled 108 tons.
[4] Figures for imports and exports cover January to September, inclusive.

Production.—The output of fuel briquets in 1941—1,298,606 net tons valued at $8,001,829—topped all previous records and represented a 24-percent increase in both tonnage and value over 1940. The increased activity in 1941 is directly traceable to efforts to meet increased fuel demands in the national emergency. If operated at its full present capacity, the industry could more than double its 1941 production. An active promotional campaign by the operators [6] has seemed to stimulate both production and sales.

Briquets were produced in 17 States. Almost half of the entire output was concentrated in Wisconsin; West Virginia and Pennsylvania followed in order, with large increases. Other States producing over 20,000 tons were, in order of importance, Oregon, Missouri, Illinois, Minnesota, North Dakota, and Michigan. Increased production was reported in all but 6 States.

Packaging of bulk briquets at the plants, amounting to 37,000 tons, was reported by 17 fuel-briquet operators; no data are available on the quantity of briquets packaged by retailers.

Production of fuel briquets in the United States, 1940–41

Large tonnages of bituminous coal moving over the Great Lakes during the summer months are stored at Lake ports. During the winter months, when the Lakes are closed, the coal is reloaded and shipped into the Northwest. The fine coal resulting from rehandling has a lower sales value than the coarser sizes, but a higher-grade product can be made by briquetting and a better sales realization obtained. The enormous supplies of bituminous slack thus made available at Lake ports has naturally made Wisconsin the nucleus of the briquetting industry. It is the only State for which production can be shown without revealing data on individual operations.

Production of fuel briquets in Wisconsin, 1936–41

Year	Plants	Net tons	Value	Year	Plants	Net tons	Value
1936	9	588, 163	$4, 178, 981	1939	10	430, 554	$3, 158, 859
1937	10	507, 462	3, 639, 183	1940	11	487, 574	3, 440, 676
1938	10	422, 281	3, 085, 873	1941	10	535, 457	3, 870, 077

There are other large plants located at coal mines, principally in West Virginia and Pennsylvania, and smaller operations at petroleum refineries and gas plants, mainly in the Pacific Coast area.

Briquets are used almost entirely for househeating; therefore, production is normally highly seasonal. In 1941, production was lowest in April, but in June—months earlier than usual—operations stepped up markedly, reaching their peak in November. Twenty of the 32 active plants operated every month of the year and only 3 less than 6 months.

According to the Weather Bureau,[7] the winter was slightly colder than normal in parts of the Atlantic coast, but in all other sections—including the North Central States, where the bulk of the consumption of briquets is concentrated—above-normal warmth prevailed.

Monthly production of fuel briquets in the United States, 1939–41, in net tons

Month	1939	1940	1941	Month	1939	1940	1941
January	113, 698	157, 091	135, 532	August	57, 267	58, 706	109, 487
February	99, 195	76, 550	118, 596	September	78, 012	84, 466	107, 257
March	58, 840	68, 981	85, 728	October	113, 315	92, 295	120, 197
April	34, 001	43, 936	27, 252	November	89, 465	128, 301	143, 339
May	51, 384	66, 449	82, 723	December	83, 579	140, 133	137, 166
June	71, 273	57, 814	105, 307				
July	42, 184	76, 148	126, 022		892, 213	1, 050, 870	1, 298, 606

Value.—Sales realizations on briquets in the widely separated producing centers in a given year vary considerably. An average value per ton for the entire industry therefore has doubtful significance because conditions under which briquets are manufactured differ in various parts of the country. The most important factors that influence the value per ton realized at any plant probably are the cost of raw materials, labor, and the price of competing fuels; hence, the general trend of fuel-briquet prices in the past 5 years is indicated best in this review by the average values in the Eastern, Central, and Pacific Coast States, as shown in the last three columns of the

[7] Mattice, W. A., The Weather of 1941 in the United States: U. S. Dept. of Agriculture Monthly Weather Rev., vol. 69, No. 12, December 1941, pp. 360–361.

first table of this chapter. These figures are not the prices paid by the consumers. Some plants are far from the markets they serve, and transportation charges and the margin of the wholesaler or retailer —sometimes both—must be added to the value at the plant.

The total value of fuel briquets manufactured in 1941 was $8,001,829 f. o. b. plant—an increase of $1,562,877 (24 percent) compared with 1940.

In the eastern part of the country the average value of $4.21 per ton is relatively low because virtually all the output comes from plants in the low-volatile bituminous fields of West Virginia and in the anthracite region of Pennsylvania, where the freight charges are not so important an item in the cost of raw fuel. In the Central States most of the raw fuel (bituminous low-volatile and Pennsylvania anthracite) comes from Lake docks, and the average value of $7.09 per ton discloses the extent to which freight charges affect value. In the Pacific Coast States, where residual carbon from the manufacture of oil gas forms the greater part of the raw fuel used, the average value dropped from $8.84 in 1940 to $8.36 in 1941.

Prices.—The following monthly fuel-briquet prices,[8] by cities, for 1941 are based upon cash delivery in 1-ton (2,000-pound) lots for retail sales to household consumers at the curb or into the customer's bin (without extra handling or additional charge).

Retail fuel-briquet prices per net ton, by cities, in 1941 [1]

[1] From monthly reports, Retail Fuel Prices by Cities, Retail Price Division, Bureau of Labor Statistics.

Number of plants.—Thirty-two plants reported commercial production in 1941; all but 2 of these (the new briquetting plant of the Coal Processing Corporation at Buckner, Ill.,[9] and that of the Scheele Coal Co. at Jackson, Mich.) were also active in 1940. Seven plants were idle in 1941; of these all but one were also idle in 1940. One idle plant—the Kleen Blox Coal Co., at Dickinson, N. Dak., which reported experimental production in 1938 and none since—went out of business. Two new plants (in Illinois and Missouri) were reported under construction in 1941, with operations to start in 1942. Of the

[8] From monthly reports, Retail Fuel Prices by Cities, Retail Price Division, Bureau of Labor Statistics.
[9] Black Diamond, St. Louis News Notes: Vol. 106, No. 12, 1941, p. 46.

five reported as under construction in 1940 to start in 1941, only one—that of the Coal Processing Corporation at Buckner, Ill.—began commercial operations in 1941.

Size of plants.—The following table classifies the plants operating in 1940–41 according to actual production as well as actual capacity; however, capacity affords a better indication of the size of the plants.

The total annual capacity of the 32 plants active in 1941, obtained from the operators' reports, is about 3,100,000 net tons. It is interesting to note that, although the industry reached an all-time high in 1941, should the demand warrant these 32 plants could provide more than twice their 1941 production.

The average output of the individual plants increased 24 percent—from 33,000 tons in 1940 to 41,000 in 1941. Twenty plants that operated every month in 1941 produced 1,074,811 tons—83 percent of the total.

Classification of briquetting plants in the United States, 1940–41, by size of output and annual capacity

Output (net tons)	Plants 1940	Plants 1941	Annual capacity (net tons)	Plants 1940	Plants 1941
Less than 2,000	5	6	Less than 5,000	2	2
2,000 and less than 5,000	5	2	5,000 and less than 10,000	2	4
5,000 and less than 10,000	3	3	10,000 and less than 25,000	7	6
10,000 and less than 25,000	8	9	25,000 and less than 100,000	13	11
25,000 and less than 100,000	6	6	100,000 and less than 200,000	4	5
100,000 and over	5	6	200,000 and less than 400,000	2	2
			400,000 and over	2	2
	32	32		32	32

Raw fuels.—The number of plants, by type of fuel used in 1941, is shown below.

Classification of fuel-briquetting plants in the United States in 1941, by kinds of raw fuel used

Kind of raw fuel used:	Plants
Anthracite and semianthracite fines exclusively	5
Mixture of Pennsylvania anthracite and bituminous	5
Bituminous:	
Low-volatile	13
High-volatile	3
Lignite	1
Semicoke (lignite char)	1
Residual carbon from pyrolysis of natural gas	1
Residual carbon from manufacture of oil gas	2
Petroleum coke	5
	[1] 36

[1] 3 plants made 2 kinds and 1 plant 3 kinds of briquets; hence the sum of these items exceeds the total number of plants.

A considerable quantity of Illinois bituminous high-volatile slack is used as raw fuel at the new briquetting plant of the Coal Processing Corporation at Buckner, Ill. It is also noteworthy that the quantity (though relatively small) of residual carbon from pyrolysis of natural gas, used at a California briquetting plant, doubled in 1941. Petroleum coke is being used increasingly in the manufacture of briquets.[10]

[10] Coal Dealer. Carbo Cok-ette Plant Running Full Blast: Vol. 38, No. 5, 1941, pp. 50–51.

The Consumers Lignite Co. at Alba, Tex.,[11] using raw Texas lignite without charring in making briquets, began to operate commercially in 1940 and also reported a small tonnage in 1941.

Raw fuels used in making fuel briquets in the United States, 1940–41

Raw fuel	Net tons		Percent of total	
	1940	1941	1940	1941
Anthracite and semianthracite culm and fine sizes	222,618	265,637	22.2	21.6
Bituminous and subbituminous slack [1]	636,312	787,722	63.4	64.1
Residual carbons from oil-gas manufacture and natural-gas pyrolysis; petroleum coke; and semicoke (lignite char)	144,167	175,043	14.4	14.3
	1,003,097	1,228,402	100.0	100.0

[1] Includes small tonnage of Texas lignite used without charring.

Seven operators reported washing their raw fuel (totaling 269,927 tons) before manufacturing it into briquets.

In 1941, as in 1940, four operations reported making more than one kind of briquet. One in Nebraska made three kinds in 1941 (petroleum coke, semianthracite, and low-volatile bituminous cubes); another in Nebraska made two kinds of cubes from petroleum coke and semianthracite. A large Wisconsin operator made small pillow briquets from a mixture of Pennsylvania anthracite and low-volatile bituminous coal as well as from low-volatile bituminous coal exclusively. The fourth, a Missouri operator, made two kinds of pillow briquets from the hard coals of Arkansas.

Production of fuel briquets, 1940–41, with reference to sources of raw fuels used

Location of plant	Net tons		Percent of increase in 1941
	1940	1941	
At or near Lake Superior or Lake Michigan coal docks	511,336	532,728	4.2
At coal mines	414,490	539,223	30.1
At or near petroleum refineries and oil- and natural-gas plants	111,667	141,405	26.6
At other locations [1]	13,377	15,046	12.5
	1,050,870	1,228,402	16.9

[1] Fall River, Mass.; Jackson, Mich.; and Omaha, Nebr.

Binders and recarbonization.—As the following table indicates, asphaltic pitch is the preferred binder in briquetting coal and coke. An approximate total of 80,000 tons of asphaltic pitch and 2,300 tons of starch and smaller amounts of other binders were used in the manufacture of fuel briquets in 1941.

Of the three plants using no binder, two briquetted the carbon residue from the manufacture of oil gas and one used low-volatile bituminous coal. The last, which has been in operation since 1936, manufactures 3¾-ounce pillow briquets by impact; capacity of the plant is about 1½ tons per hour and impact pressures of 50,000 to 60,000 pounds per square inch are obtained; the entire production is consumed locally.

[11] Coal Age, Texas Lignite Mine—Develops Method of Briquetting in Struggle for Markets vs. Gas and Oil: Vol. 46, No. 11, 1941, p. 51.

No operators in 1940 or 1941 reported recarbonization of briquets to drive off smoke after leaving the presses. Whether the finished product will be of the smoky type or not depends primarily on the type of raw fuel used; if the raw fuel is smoky, the briquet will be also.

Classification of briquetting plants in the United States in 1941, by type and percentage of binder used

Type of binder	Plants	Production: Net tons	Production: Percent of total	Ratio of binder to raw fuel (by weight)	Plants	Production: Net tons	Production: Percent of total
Asphaltic pitch	[1] 24	1,024,902	78.9	Less than 5 percent	4	165,194	12.7
Mixed pitches	2			5 and less than 7 percent	13	438,852	33.8
Asphalt and starch	1	200,087	15.4	7 and less than 9 percent	10	620,943	47.8
Starch	2			9 percent and over	2		
No binder	[2] 3	73,617	5.7	No binder	[2] 3	73,617	5.7
	32	1,298,606	100.0		32	1,298,606	100.0

[1] One plant also uses a nearly equal amount of unspecified binder.
[2] Two plants use residual carbon from manufacture of oil gas, and 1 uses bituminous coal as raw fuel.

Weight and shape.—Pillow-shaped briquets predominate in the United States. Of the total production in 1941, 26 of the 32 active plants produced 921,310 tons (71 percent) of pillow-shaped briquets; with one exception—the new plant of the Coal Processing Corporation at Buckner, Ill., which makes so-called "Fireballs" weighing 11 ounces each—these pillow briquets weigh from 1¾ to 5 ounces. Three plants produced 359,395 tons (28 percent) of cylindrical type and three plants 17,901 tons (about 1 percent) of cube-shaped briquets.

According to reports received, only one plant made briquets in more than one shape in 1941—an operator in Wisconsin who produced a square-pillow type of a mixture of Pennsylvania anthracite and bituminous low-volatile and a modified-pillow type of bituminous low-volatile.

Two plants made two sizes—one in Nebraska made a 20-ounce petroleum-coke cube, and a 24-ounce semianthracite cube as well as a 24-ounce bituminous low-volatile cube; the other in Wisconsin (the plant referred to above) made a Pennsylvania-anthracite and bituminous low-volatile pillow briquet (2 by 2 by 1¼ inches) and a bituminous low-volatile modified-pillow briquet (2 by 1½ by 1¼ inches).

Prevailing weight of briquets produced in the United States in 1941

Weight (ounces)	Plants	Production: Net tons	Production: Percent of total	Weight (ounces)	Plants	Production: Net tons	Production: Percent of total
Less than 2	4	67 [illegible]	5.2	6 and under 10			
2 and under 3	13	744,[illegible]	57.3	10 and under 16	1	50,414	3.9
3 and under 4	6	347,083	26.7	16 and under 25	3		
4 and under 5	4	89,294	6.9		32	1,298,606	100.0
5 and under 6	1						

Distribution.—Shipments of briquets during 1941, as reported by the operators, increased 22 percent over 1940. Briquets are used widely in the United States; in 1941 they were shipped into 39 States, the District of Columbia, and Alaska and exported to other countries.[12]

Shipments from each producing State cannot be shown because there are only one or two producers in each of the States except Wisconsin and confidential reports of individual companies would thus be revealed. However, a graphic presentation of the centers of production with corresponding States of destination for 1928 and 1936 is included in Minerals Yearbook, 1937 (p. 965, fig. 65).

Shipments by truck in the Central States increased in 1941. Generally, rail movement represents shipments to considerable distances and shipment by truck represents local and nearby consumption.

Shipments of fuel briquets of domestic manufacture, 1940–41, by States of destination, in net tons

[1] Includes local deliveries.

Imports and exports.—Before 1922 the quantity of fuel briquets imported into the United States was negligible. The anthracite shortages of 1922–23 and 1925–26, however, created a demand for the European product (mostly from Germany, Belgium, and France, and mainly for consumption in the anthracite-consuming States), which in 1926 reached a record of 123,593 net tons. Imports continued at a comparatively high level in the following years; in 1932 they amounted to 80,288 tons but thereafter dropped sharply and since September 1939 have virtually ceased, the last overseas shipment (1,344 net tons), from Belgium to Massachusetts, arriving in February 1939. The

[12] See table of exports for quantities exported.

only record of imports since 1939 covers a shipment of 108 tons from Canada to Alaska in 1941.

Figures for imports of briquets since 1919, the first year of record, are included in annual volumes of Mineral Resources and Minerals Yearbook.[13]

Briquets (coal and coke) and other composition coals for fuels imported for consumption in the United States, 1937–41

Year	Net tons	Value	Year	Net tons	Value
1937	6,674	$28,549	1940		
1938	13,814	67,366	1941 (Jan.-Sept.)	108	$548
1939	1 344	5,752			

Briquets (coal and coke) exported from the United States, 1937–41 [1]

Year	Net tons	Value	Year	Net tons	Value
1937	25,350	$166,369	1940	23,285	$161,619
1938	16,692	123,309	1941 (Jan.-Sept.)	27,301	199,351
1939	12,576	97,725			

[1] Data for 1937–40, by countries and customs districts, shown in earlier reports of this series.

World production.—Official data on production of fuel briquets in other countries since 1939 have been meager, owing to the war. Any possible revisions will be made in forthcoming issues of this series.

World production of fuel briquets, 1937–41, by countries, in metric tons [1]

[1] In addition to the countries listed, briquets are produced in Canada and New Caledonia, but data on output are not available.
[2] Data not available.
[3] Data for year ended March 31 of year stated.
[4] January to June, inclusive.
[5] Includes packaged fuel as follows—1937: 132,482 tons; 1938: 146,012 tons; 1939: 195,504 tons; 1940: 258,105 tons; 1941: 244,797 tons.
[6] Totals incomplete; they represent sum of figures given in table only.

[13] 1919–29, Mineral Resources, 1929, part II, p. 32; 1930–35, Minerals Yearbook, 1936, p. 657; 1936, Minerals Yearbook, 1937, p. 964.

PACKAGED FUEL

Packaged fuel differs from fuel briquets in that the former is a more or less friable product wrapped to withstand weathering and breakage and designed primarily for local or nearby consumption. The packages, tightly wrapped in heavy paper and sealed with gummed tape, consist of 3- to 4-inch cubes (six to a package, weighing 10 to 15 pounds). Packaged fuel is made from various types of high-quality coal or coke screenings, usually mixed with a neutral binder. Its growth in popularity has been due largely to convenience and cleanliness in handling and to the fact that it may be purchased in less-than-ton lots. The output of packaged fuel, which rose so rapidly from 1935 to 1940, dropped in 1941 for the first time and was 5 percent less than in 1940, amounting to 269,844 tons valued at $2,471,567 in 1941.

The war is seriously affecting the packaged-fuel industry. The increased cost of raw fuels and labor and the shortages of paper, glue, etc., as well as competition within the industry itself, have reduced production at many plants and forced a number of others out of business. Machinery manufacturers reported virtual stoppage of sales for new installations in the summer and fall of 1941. One reported that five orders for installation of completely automatic packaged-fuel machines were canceled in the United States and two in Canada because paper supplies were not available; and another reported diversion of his business to construction of special machines for briquetting ores and metal wastes for war work. Over 2 million pounds of paper were required to wrap the packaged fuel produced in 1941. However, it is believed that, if paper requirements can be even partly met, the industry will continue to operate during the emergency, because clean packaged fuel has proved attractive to many consumers.

The record of 62 plants, which began operations between 1935 and 1938 and were active each year through 1941, would indicate definitely that the industry was firmly established before the paper shortage. There seems to have been a gradual trend toward fewer but larger plants to reduce costs; but smaller units probably will continue to operate in isolated sections.

Of the operators producing packaged fuel in 1941, one-third reported wrapping their product by machine, one-third by hand, and one-third partly by machine and partly by hand.

Although packaged fuel is manufactured principally for local or nearby consumption, in 1941 eight operators reported shipping 4,399 tons by rail and 11,382 tons by truck within a radius of 500 miles.

Processes.—No new processes or types of machinery for use in the packaged-fuel industry were reported by United States operators in 1941. Eighty manufacturers used the Eberling process [14] in 1941; others used the Glenn-Smith [15] and Leemon [16] processes; and one—the Johnson Coal Cubing Co.,[17] of Detroit, Mich., largest operator since 1932—uses a process and equipment of its own design. These

[17] Black Diamond, A Mammoth Package Fuel Plant: Vol. 102, No. 7, April 8, 1939, p. 23.

processes are discussed in earlier reports of this series and in the trade journals.

In 1941, several packaged-fuel plants using the "cold-mix" method started fluxing briquetting mixtures with live steam to improve the binding properties of starch and to increase the rate of drying the finished packages, and some have reported favorable results.[18]

In 1939 the Viking Machinery Co. of Jackson, Mich., developed a process and machine for making packaged fuel, which comprises the manufacture of binder from off-grade grains at the briquetting plant, hot mixing of this prepared grain binder with the coal, making the cubes by mechanical vibration and tamping action and automatically wrapping the cubes. The entire operation except the transfer of the wrapped cubes to the drying conveyor is automatic. The Consolidation Coal Co., Windsor, Ontario, is reported to be successfully operating these machines 24 hours a day and to be unable to supply the demand. The plant is significant in that it, along with a few others in the United States, indicates a trend toward well-engineered packaged-fuel plants of greater capacity rather than small plants in retail yards. No plants in the United States are at present equipped with this machinery; five contracts for such installations in the States were canceled in 1941 owing to paper shortage and priorities.

Salient statistics of the packaged-fuel industry from 1936 to 1941 are summarized in the following table; 1935 is the first year for which these data were collected by the Bureau of Mines.

Salient statistics of the packaged-fuel industry in the United States, 1936–41

[Data regarding fuel briquets are given separately at beginning of this chapter]

Year	Production (thousands of net tons)			Value of production (thousands of dollars)	Plants in operation	Average output per plant (thousands of net tons)	Average value per net ton, f. o. b. plant	
	Eastern and Pacific Coast States	Central States	Total				Eastern and Pacific Coast States	Central States
1936	6	60	66	505	48	1	$8.84	$7.49
1937	10	136	146	1,287	64	2	9.62	8.76
1938	9	152	161	1,405	76	2	9.92	8.66
1939	9	207	216	1,867	103	2	9.69	8.62
1940	8	277	285	2,392	106	3	10.12	8.36
1941	10	260	270	2,472	103	3	10.95	9.09

Production and value.—The 103 active plants, all but 7 of which are in the Central States, produced 269,844 net tons valued at $2,471,567 in 1941 (see fig. 2). Production for the first time decreased—5 percent less than in 1940—but the value increased 3 percent.

Output declined in all but 4 of the 13 States producing packaged fuel; the States showing increases were Maine, Illinois, Iowa, and Missouri. However, Michigan, Ohio, and Wisconsin (in order named) continue to be the largest producers.

The increase in value probably is accounted for by the higher costs of raw materials and labor.

[18] From study in preparation by V. F Parry, Technologic Branch, Bureau of Mines, Golden, Colo.

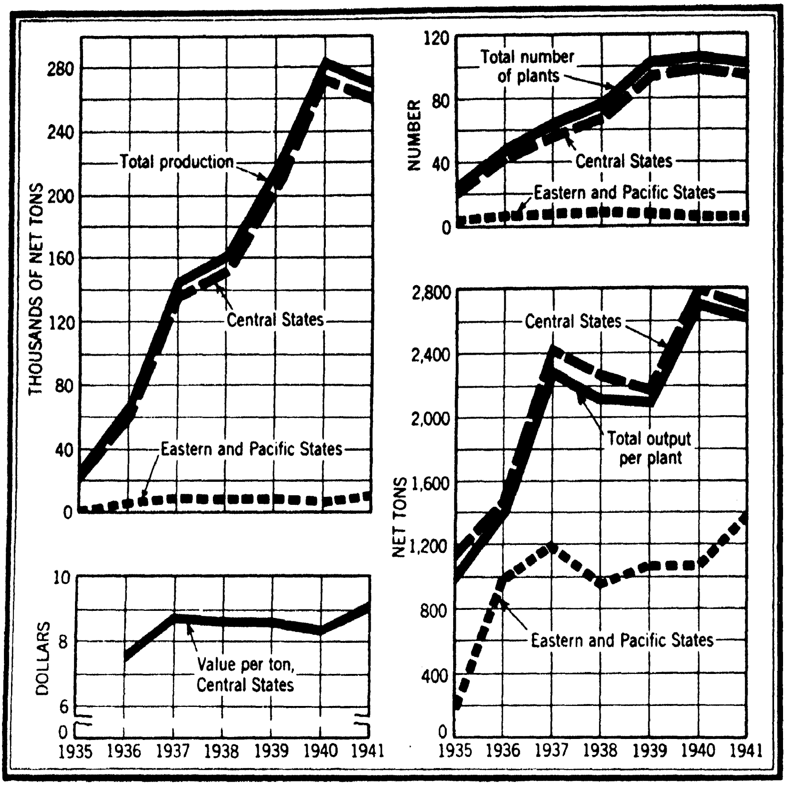

FIGURE 2.—Production of packaged fuel, number of plants in operation, output per plant, and average value per ton, f. o. b. plant (Central States), 1935-41.

Production of packaged fuel in the United States, 1940-41, by States

[The plants and production in this table are not included in the preceding fuel-briquet tables]

[1] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[2] Includes States entered as "(1)" above.
[3] Maine 2, Pennsylvania 1, Virginia 3, and Washington 1.

The values, by States, in the following table represent the average per ton received by operators in 1940 and 1941 and show the increased average realization at plants in 1941; similar advances also obtained in the other six producing States but cannot be shown because there were less than three operators in each State. As many plants sell to both consumers and retailers, the values do not represent the price per ton to consumers but indicate the average per ton received by producers on the total product (exclusive of delivery charges). The value at the plant comprises cost of coal at mine, freight rate, direct manufacturing cost, indirect manufacturing cost, and profit.

Average value received per net ton of packaged fuel, 1940–41

State	1940	1941	State	1940	1941
Illinois	$9 58	$10.69	Missouri	$7.14	$8 19
Indiana	7 81	9 06	Ohio	8 29	9 23
Michigan	7 93	8.54	Wisconsin	8 67	9.15
Minnesota	10 15	10 82			

The peak producing season is generally from October through April. The sharp rise beginning in September 1940 continued through March 1941 but dropped sharply in April and May. Production for the 1941–42 heating season was behind the previous season's record from September through December 1941—due largely to the warmer-than-normal temperatures in the North Central States that produce most of the output.

Twenty-nine plants operated each month of the year, 58 from 7 to 11 months, and 16 from 2 to 6 months.

Monthly production of packaged fuel in the United States, 1940–41, in net tons

Month	1940	1941	Month	1940	1941
January	36,160	39,594	August	7,350	10,184
February	29,460	37,727	September	21,680	17,422
March	34,035	40,893	October	29,564	27,183
April	31,518	17,592	November	36,181	30,506
May	17,429	6,318	December	35,656	30,296
June	2,811	5,028			
July	2,669	7,101		284,513	269,844

Number of plants.—One hundred and three plants reported production of packaged fuel on a commercial scale in 1941 (3 less than in 1940); 96 of these were also active in 1940, but 6 additional plants—in Michigan, Minnesota, and Missouri—began operations on a small scale in 1941. Eight of the 103 plants went out of business after operating part of the year.

Fourteen plants went out of business in 1941—the same number as in 1940. Since 1935 many plants have established themselves firmly and built up a stable business; however, during the development period of the packaged-fuel business a relatively large number of plants began to operate and soon thereafter went out of business. Records show that from 1935 to 1941, inclusive, of the 133 plants starting operations 43 went out of business. Cost of raw materials, prices of competing fuels, and, more recently, shortages of paper and

other equipment are influencing factors in the decreased packaged-fuel production and number of plants in operation. There seems to be considerable competition within the industry itself in cities having numerous packaged-fuel operations—notably in Detroit, Mich., and Cleveland, Ohio, each with more than 10 such plants. [19]

Activity in number of packaged-fuel plants, 1936–41

Year	Active	New	Idle	Out of business	Year	Active	New	Idle	Out of business
1936	48	23	5	2	1939	103	29	11	9
1937	64	17	6	3	1940	106	16	15	14
1938	76	16	8	1	1941	103	[1] 7	[2] 8	[3] 14

[1] 4 in Michigan and 1 each in Indiana, Minnesota, and Missouri; all but 1 active in 1941.
[2] 4 in Ohio and 1 each in Idaho, Indiana, Michigan, and Missouri; 5 of these were also idle in 1940.
[3] 6 in Michigan, 2 each in Minnesota, Ohio, and Indiana, and 1 each in Missouri and Wisconsin; 11 of these were active in 1940.

Size of plants.—The average annual production per plant dropped slightly—from 2,700 tons in 1940 to 2,600 in 1941.

Reports submitted on individual capacity for 1941 indicate that the 103 active plants were equipped to produce about 698,000 tons (2.6 times the 1941 production) if operated at full capacity throughout the year. Few plants reported installation of additional equipment or replacements in 1941.

Classification of packaged-fuel plants in the United States, 1940–41, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1940	1941		1940	1941
Less than 500	[1] 23	[2] 25	Less than 5,000	62	68
500 and less than 1,000	19	19	5,000 and less than 10,000	25	17
1,000 and less than 3,000	40	39	10,000 and less than 15,000	6	6
3,000 and less than 5,000	10	5	15,000 and less than 25,000	7	6
5,000 and less than 10,000	9	9	25,000 and less than 40,000	5	5
10,000 and less than 25,000	4	5	40,000 and less than 60,000		
25,000 and over	1	1	60,000 and over	1	1
	106	103		106	103

[1] 4 of these began operations in the fall of 1940.
[2] 2 of these began operations in the fall of 1941.

Raw fuels.—The tonnage of raw fuels used in the manufacture of packaged fuel in 1941 totaled 266,818 net tons. Low-volatile bituminous slack continued to be the principal raw fuel used, representing 80 percent of the total; petroleum coke, Arkansas semianthracite, high-volatile bituminous, and coke breeze followed in the order named. Petroleum coke rose significantly from 5 percent of the total raw fuels used in 1939 to over 18 percent in 1941; this type of packaged fuel is now made in Illinois, Iowa, Minnesota, Missouri, Nebraska, Ohio, Washington, and Wisconsin. Coke breeze, combined with petroleum coke, was reported for the first time in 1941 by an operator in Missouri.

[19] Black Diamond, In the Realm of the Retail Merchant—Detroit Retailers Spend Enormous Sums for Price-cut Newspaper Ads: Vol. 106, No. 3, February 8, 1941, pp. 16, 46.

In 1941, low-volatile bituminous cubes were made at 90 plants, petroleum-coke cubes at 11, semianthracite cubes at 2, and high-volatile bituminous cubes at 1; cubes of mixtures of the various raw fuels were made at 5 plants. Six operators made more than one kind, and three operators made cubes in two sizes.

Of the total raw fuels used, about 215,000 tons (81 percent) were shipped-in slack from the mines and from the Lake docks; the remainder (about 52,000 tons or 19 percent) represents the yard screenings used. Of the 103 operations in 1941, 51 operators used shipped-in slack exclusively; 29 packaged their yard screenings only; and 23 used both shipped-in slack and yard screenings.

Raw fuels used in making packaged fuel in the United States, 1940–41

Raw fuel	Net tons		Percent of total	
	1940	1941	1940	1941
Bituminous (high-volatile) and semianthracite	4,898	4,784	1.7	1.8
Bituminous (low-volatile)	245,881	213,474	87.4	80.0
Petroleum coke	30,555	[1] 48,560	10.9	18.2
	281,334	266,818	100.0	100.0

[1] Includes small tonnage of coke breeze.

Binders.—Cornstarches of various types, averaging about 15 pounds per ton of packaged fuel produced, are the principal binders. Cement, asphalt, and sulfite cellulose—either alone or in combination with starch—were also employed. An approximate total of 1,800 tons of starch and 1,500 tons of asphaltic pitch and smaller amounts of other binders were used by operators of packaged-fuel plants. The following table classifies the packaged-fuel plants in 1941 according to type and percentage of binder used.

Classification of packaged-fuel plants in the United States in 1941, by type and percentage of binder used

Type of binder	Plants	Ratio of binder to raw fuel (by weight)	Plants
Starch	91	Less than 0.5 percent	
Starch and cement	3	0.5 and less than 1 percent	71
Starch and asphalt	1	1 and less than 2 percent	26
Cement	5	2 and less than 3 percent	4
Asphalt	2	3 and less than 5 percent	
Sulfite cellulose	1	5 percent and over	2
	103		103

PEAT

By Joseph A. Corgan

SUMMARY OUTLINE

Peat production in 1941 amounted to 86,503 short tons valued at $657,556, a substantial increase over the 1940 output of 70,097 tons valued at $516,865. The 1941 output, although the largest since the World War of 1914–18, did not equal the peak United States production of peat products in 1918—107,261 tons. The 1918 output was produced by 25 plants operating in 13 States, whereas the 1941 production came from 49 operators in 17 States; thus it would seem that should there be an increased demand (such as was experienced in 1918) for peat from domestic sources the peat industry today, being more widespread and comprising more producing plants, will be better equipped to fill it.

Imports of peat moss have been curtailed drastically on account of the war. During the first 9 months of 1941, 22,127 short tons of peat moss valued at $507,856 were imported into the United States; owing to censorship, imports for the last 3 months of the year cannot be published. In 1940 peat-moss imports totaled 21,689 tons valued at $454,632; and in 1939, before the war became world-wide, imports were 78,611 tons with a reported value of $1,204,883. Although a decrease in foreign supplies of peat moss will no doubt inconvenience regular consumers, an opportunity is presented to producers in the United States to develop their deposits and expand the market for the domestic product.

A directory listing the names and addresses of operators who reported their production in 1941 to the Bureau of Mines has been prepared and will be sent, upon request, to those who may be interested.

Reserves.—About one-half of the States contain some peat reserves, which constitute an important asset to the natural resources of the country. The total, calculated as air-dried peat, has been estimated at 13,827,000,000 short tons.[1]

PRODUCTION

The increase in domestic production from 70,097 short tons in 1940 to 86,503 tons in 1941 probably was due in part to the restriction of imports from foreign countries.

The 1941 output showed an increase of 23 percent in quantity and 27 percent in value over 1940. The average value a ton in 1941 was

[1] Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

$7.60 compared with $7.37 and $6.53 in 1940 and 1939, respectively. The production and value of peat for the years 1936 to 1941 are shown in the following table.

Peat produced in the United States, 1936–41

Year	Short tons	Value	Year	Short tons	Value
1936	46,126	$266,883	1939	55,483	$362,066
1937	51,223	305,156	1940	70,097	516,865
1938	45,933	286,127	1941	86,503	657,556

The trend of peat production and value is presented graphically in figure 1 for 1908 to 1926 and 1934 to 1941. The Federal Government made no canvass of the peat industry from 1927 to 1933, inclusive, and no data for these years are available.

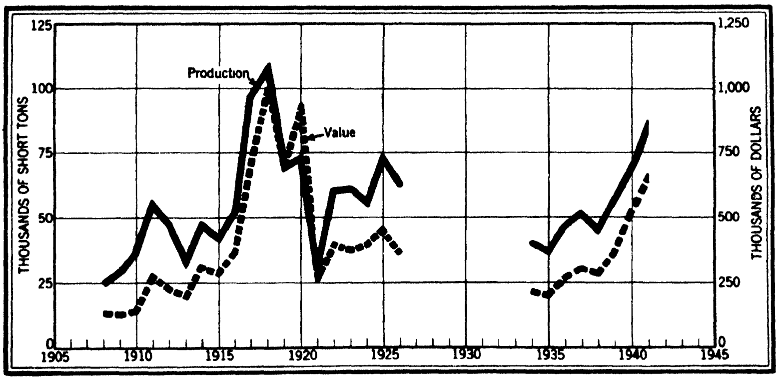

FIGURE 1.—Quantity and value of peat production, 1908–41; no data available for 1927–33

Forty-nine operators in 17 States reported to the Bureau of Mines in 1941, a decrease of 1 producer compared with 1940; however, in 1940 reports were received from only 15 States. Thus, the industry is more widespread and should be better equipped to handle an increased demand for peat.

In 1941 the producing States, in order of output, were: New York, Illinois, New Jersey, Michigan, Maine, Iowa, Pennsylvania, California, Connecticut, Colorado, Florida, Wisconsin, Ohio, Minnesota, Massachusetts, Washington, and New Hampshire.

Of the total production, peat humus represented 41 percent; reed or sedge peat, 40 percent; and moss peat and other, 19 percent. Peat humus was produced in 12 States; reed or sedge peat, in 9 States; and moss peat and other in 9 States.

Thirty-six plants reported production of shredded peat; 17. raw peat; and 8, cultivated peat.

USES

As for many years in the past, a large percentage of the sales of peat in the United States has been for soil improvement. The reports of sales indicate that 75 percent was sold for this purpose in 1941; 20

percent for use in mixed fertilizers; and 5 percent for other uses, including litter for barns and poultry yards. Peat is utilized to some extent also as a packing material for fruits, vegetables, shrubs, and fragile articles. No sales of peat for fuel purposes were reported. Peat is burned extensively in some European countries as a fuel, and reports indicate that because of the dislocation of fuel supplies throughout the war zone efforts are being made to extend its use, in order that the deficiency in customary fuels may be partly filled. In the United States, with its plentiful supplies of higher-grade fuels, peat has not been able to compete on a commercial scale, although in 1918, during the World War, 20,567 tons were used for fuel purposes.

It is of interest to note that during the World War of 1914–18, moss peat was collected for surgical dressings and 595,540 [2] moss-peat pads were prepared in this country and used in military hospitals both here and in Europe. Most of the moss peat was gathered from Maine, Oregon, and Washington bogs, and the pads were prepared under the direction of the American Red Cross. It has not been found necessary to do any work of this kind during the present war because of the plentiful supply of cotton and available facilities for making surgical dressings and pads from that material.

United States Government specifications.—There are great differences in the kinds of peat, both as to character and value for specific uses. In purchasing its peat requirements, the Federal Government has certain specifications that must be met. These specifications may be obtained from the Procurement Division, United States Treasury Department, Washington, D. C.

IMPORTS [3]

The decrease in peat-moss imports in 1940 and for the January-September period of 1941 may be attributed to a shortage of shipping facilities and general dislocation of commerce because of the war. For the first 9 months in 1941, imports totaled 22,127 short tons with a reported value of $507,856. Imports in 1940 amounted to 21,689 tons valued at $454,632, and in 1939 (the last year that might be considered normal), imports were 78,611 tons valued at $1,204,883.

Before 1940, Germany was for many years the principal exporter of peat to the United States. In 1939, imports from Germany were 28,127 tons valued at $389,597. In 1940 only 41 tons were imported from Germany, and during the first 9 months of 1941 only 15 tons were received from that country.

Peat moss imported for consumption in the United States, 1936–41

Year	Short tons	Value	Year	Short tons	Value
1936	75,066	$955,807	1939	78,611	$1,204,883
1937	86,871	1,219,127	1940	21,689	454,632
1938	69,509	1,092,942	1941 (Jan.-Sept.)	22,127	507,856

[2] Hotson, J. W., Sphagnum from Bog to Bandages: Washington Univ. Puget Sound Biol. Sta. Pub., vol. 2, No. 47, 1919, pp. 213, 243.
[3] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Sweden and the Netherlands exported substantial quantities of peat to the United States before 1940, but in the January–September period of 1941 no imports were received from these countries. Except for the 15 tons received from Germany, all imports in the January–September period of 1941 came from Canada and the United Kingdom. The average value of the imported product per ton increased from $20.96 in 1940 to $22.95 in the first 9 months of 1941. These values show a large increase over 1939 and 1938, when the averages were $15.33 and $15.72, respectively.

Peat moss imported for consumption in the United States, 1940–41, by countries

WORLD PRODUCTION

Data on production of peat throughout the world are exceedingly incomplete, principally because of the war. The following table shows statistics for most countries in 1938 and 1939 and information available for 1940 and 1941.

World production of peat, 1938–41, by countries [1]

[Compiled by B. B. Waldbauer]

Country [1]	1938	1939	1940	1941

[1] In addition to the countries listed, Argentina, Austria, Eire, Finland, France, Germany, Hungary, Italy, Norway, and Poland produce peat, but data of production are not available.
[2] Data not available.
[3] Estimated.

CRUDE PETROLEUM AND PETROLEUM PRODUCTS[1]

By A. G. White, G. R. Hopkins, H. A. Breakey, and A. T. Coumbe

SUMMARY OUTLINE

GENERAL REVIEW

A material expansion in normal business, combined with the rapidly growing production of war materials for domestic defense and export, raised the total demand for oil products above all former records in 1941.

Compared with 1940, there was a further substantial decline in this Nation's exports and an increase in imports from other American countries. As the net exports were reduced to less than 1 percent of total demand, the major factor in 1941 was the growth in domestic demand. The total domestic demand for all oils was about 11 percent higher than in 1940, giving an increase of 12 percent for motor fuel, 12 percent for residual fuel oils, 8 percent for distillate fuel oil, 20 percent for lubricating oils, and 26 percent for asphalt.

World production of crude petroleum in 1941 was less affected by the war than might have been expected; it is estimated at approximately 2,227 million barrels—an increase of 85 million barrels or approximately 4 percent. About 51 million of this increase was in the United States, whereas a gain of 38 million barrels is indicated for Venezuela and 20 million for Russia. The principal declines were 12 million barrels in Iraq, 8 million in the Netherlands Indies, and 4 million in Rumania.

Production in the United States was supplemented by a withdrawal of about 18 million barrels from stocks of domestic crude oil as compared with an increase of 23 million barrels in 1940. The demand for domestic crude oil in the United States rose from 1,330 million barrels in 1940 to 1,422 million in 1941—a gain of 92 million barrels or about 7 percent.

During 1941, crude runs to stills and crude production showed constant acceleration. Crude runs totaled 1,409 million barrels—a

[1] Data for 1941 are preliminary; detailed statistics with final revisions will be released later.

daily average of 3,861,000 barrels or a 9-percent gain over 1940. Crude production for the year amounted to 1,404 million barrels—a daily average of 3,847,000 barrels or a gain of about 3.8 percent over 1940. Stocks of all oils declined about 11 million barrels in 1941, representing a decrease of almost 19 million barrels in all crude stocks, a decline of over a million barrels in natural-gasoline stocks, and an increase of over 9 million barrels in stocks of refined oils.

Total demand for all oils in the United States, 1932–41

[Millions of barrels]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1932	835.5	103.3	938.8	1937	1,169.7	172.8	1,342.5
1933	868.5	106.7	975.2	1938	1,137.1	193.7	1,330.8
1934	920.2	114.5	1,034.7	1939	1,231.1	188.9	1,420.0

[1] Subject to revision. [2] Not available.

As import and export data for the last quarter of 1941 cannot be published, no exact figures of demand, by products, are available. The total demand for all oils increased more than 8 percent compared with 1940. During the first 9 months of 1941, compared with the same period of 1940, total exports were 27 million barrels less, total imports gained about 7 million barrels, and domestic demand for all oils increased about 114 million barrels, or almost 12 percent.

In the first quarter of 1941, the demand for all oils gained only 2.6 percent over the same period in 1940. Exports reached the lowest level and were only 19.7 million barrels for the quarter. The demand for heating oils increased to only a slight degree in comparison with the demand during the abnormally cold weather in the first quarter of 1940. The production of crude petroleum averaged 3,603,000 barrels daily, and about 2.6 million barrels were added to crude stocks of domestic origin. Daily average runs to stills of 3,580,000 barrels were supplemented by a reduction of 7.1 million barrels in stocks of refined oils. The increase in gasoline stocks was less than normal, and the peak of 98.7 million barrels of finished and unfinished gasoline stocks on March 31 was about 5 million barrels less than on the same date in 1940.

In the second quarter of 1941, the demand for all oils increased 7.8 percent over that in the same period of 1940. Total exports for the quarter rose to 26.5 million barrels. Crude production increased to a daily average of 3,770,000 barrels and was supplemented by a reduction of 8.1 million barrels in crude stocks of domestic origin. Runs to stills averaged 3,808,000 barrels daily, with a total gain of about 1.4 million barrels in stocks of refined oils. The loan of tankers to Great Britain reduced movements from the Gulf and led to curtailment of gasoline deliveries to distributors in the East Coast area in an effort to build up stocks of fuel oils to meet the winter peak demand.

In the third quarter of 1941, the demand for all oils gained 13.9 percent compared with the same period of 1940. Total exports rose to 29.1 million barrels in spite of the discontinuance of shipments to Japan in early August. Crude production rose to a daily average of

3,903,000 barrels, and daily runs to stills averaged 3,992,000 barrels. Crude stocks of domestic origin declined 13.6 million barrels during the quarter, but stocks of refined oils rose 7.2 million barrels. The return of tankers loaned to Great Britain combined with restricted gasoline consumption in the East Coast district resulted in the rise of stocks of all oils in that district to 76.6 million barrels on September 30, a point still 5 million barrels below the stocks on the same date in 1940.

In the fourth quarter of 1941, the demand for all oils was approximately 9 percent above that for the same period in 1940. Exports continued to increase. Exceptionally mild weather reduced heating-oil demand below normal expectations, and stocks of all oils in the East Coast area reached a peak of 81.7 million barrels on November 30—a point 6.4 million barrels higher than on the same date in 1940. Crude production averaged 4,106,000 barrels daily for the quarter and runs to stills were 4,058,000 barrels daily; both figures represented new quarterly records. Crude stocks of domestic origin increased about 0.8 million barrels, and stocks of refined oils rose 8 million barrels. Stocks of finished and unfinished gasoline showed an abnormal increase of over 14 million barrels during the quarter and totaled 94.1 million barrels on December 31—almost 10 million barrels more than on December 31, 1940.

[3] For comparison with 1941.

Just before the United States entered the war, serious consideration was being given to the maintenance of crude production and refinery operations at even higher levels in expectation of a possible 5- to 10-percent increase in total demand during 1942. The whole trend of expected demand was reversed, however, by the subsequent loss of the principal sources of rubber supply and the curtailment of oil consumption in the major East Coast market owing to necessary readjustments in tanker transportation.

Fortunately for the East Coast area, the threatened shortage of supply due to diversion of tankers in the summer of 1941 had paved the way for initiating the steps necessary to increase overland tank-car movements, construct new pipe lines, speed tanker movements, pool supplies, and distribute extra costs. These measures and unusually mild fall weather combined to maintain stocks in the East Coast district at a high point to the end of 1941 and made it possible to bridge peak winter demand without serious inconvenience.

By February 1942 a drastic cut in expected domestic gasoline demand became apparent in consequence of the decreased use of automobiles to save wear on tires. By March, steps were taken to conserve the dwindling stocks of oil in the East Coast area by curtailing deliveries of gasoline to distributors one-third, and by May gasoline ration cards were in use. With prospects of a heavy cut in civilian gasoline consumption in 1942, runs to stills and the demand for crude oil began to drop far below expectations. This decline in runs was accentuated by the large stocks of gasoline on hand, by the problems of readjustment in refinery yields to produce more fuel oils and less gasoline, by changes in transportation routes at higher costs, and by the problem of price adjustments involved in the new movements and in the relatively greater output of heavy fuel oils required.

The long-term trends of supply and demand are shown in figure 1.

The experience of the United States duplicates that of other countries, in that the direct and indirect effects of war tend to curtail civilian consumption of petroleum and thus offset increased military requirements. In nearly every instance the forecasts of large total increases in wartime consumption have proved erroneous. As regards this nation, the total oil supply and demand are so large that direct military and naval requirements are not likely to comprise more than a fraction of normal demand, and the effect on civilian consumption would naturally be less drastic.

Naval use of fuel oil generally increases three to four times over peace-time requirements in war time. In the World War of 1914–18 the supply of naval fuel oil was a major problem, accentuated by almost complete conversion of navies from a coal-burning basis in 1914 to an oil-burning basis in 1918. The tremendous expansion in air warfare is characteristic of present war operations and doubtless will greatly increase the relative amount of gasoline required, as evidenced by the program initiated in 1941 to increase 100-octane aviation-gasoline capacity threefold.

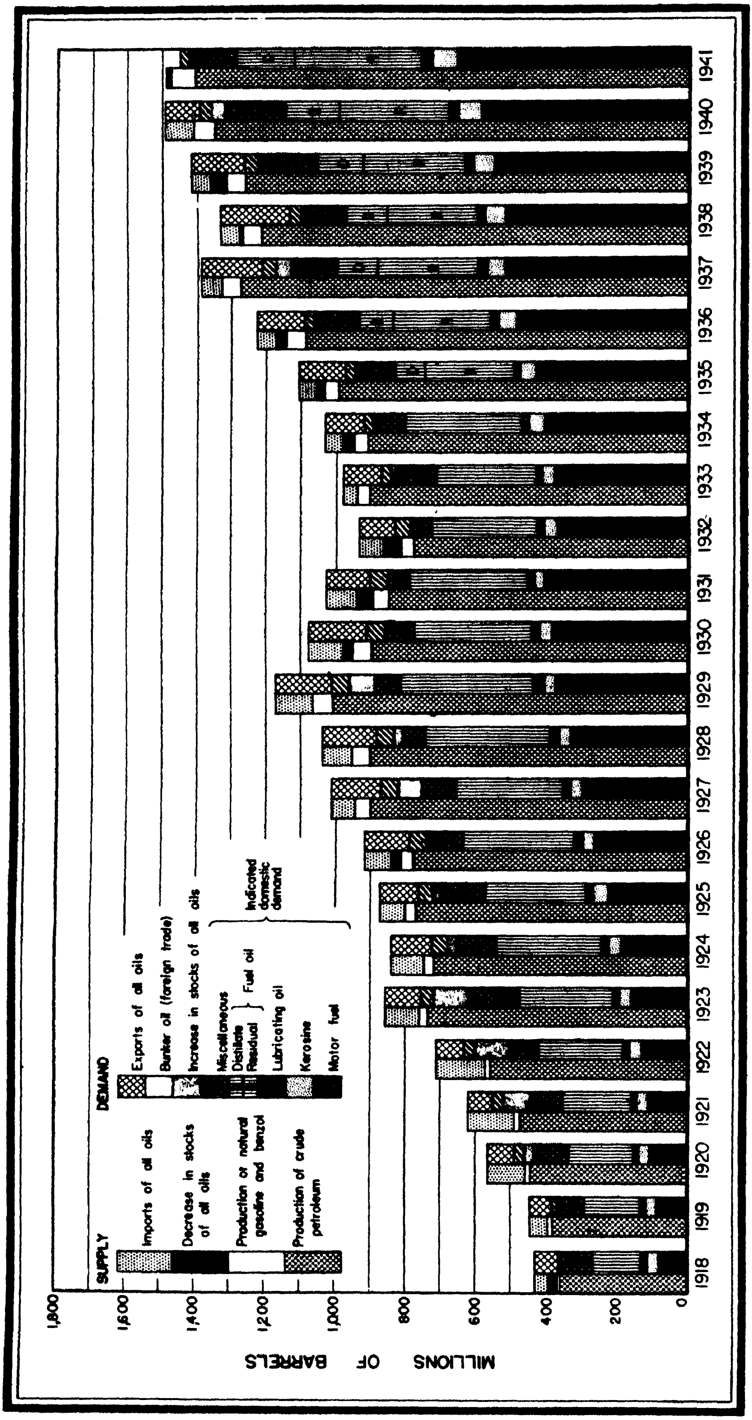

FIGURE 1.—Supply and demand of all oils in the United States, 1918–41.

RESERVES

Reserves of crude oil on January 1, 1942, were estimated by the American Petroleum Institute Committee on Petroleum Reserves at 19,589,296,000 barrels. These reserves include only crude oil and distillate, in known and proved fields, that are recoverable by present production methods. New discoveries in 1941 totaled 1,968,963,000 barrels, or 564,781,000 barrels more than was produced. Even though reserves are at the highest point they have ever reached, it is notable that there have been no large new discoveries in recent years. Of the additions to reserves in 1941, 1,538,989,000 barrels represented further development of fields discovered before 1941, leaving only 429,974,000 barrels as actual new field discoveries.

LEGISLATION AND ADMINISTRATION

Little legislation affecting the oil industry was promulgated in 1941; but administrative acts, either by the President of the United States or by administrators or boards appointed by him, had a material influence on the petroleum industry. Congressional action that affected the industry included passage of the Lend-Lease Act; passage of the Cole Pipe Line Act, giving pipe lines the right of eminent domain when needed for national defense; extension of the Interstate Oil Compact for 2 years; investigation of the East coast oil shortage; and passage of the Bland Act, raising load limits on tankers.

The administrative acts affecting the industry were the appointment of a Petroleum Coordinator by the President; requests and orders by the Office of Price Administration and Civilian Supply affecting prices; priority rulings by the Office of Production Management and Priorities and Allocation Board (both later merged into the War Production Board), not only for the purpose of allocating steel and other deficient commodities, but also for enforcing rulings by other boards; limitation of earnings of pipe-line companies to 8 percent of their valuation, by order of the Interstate Commerce Commission; Presidential prohibition of exports of filled and empty oil drums, except under license; loan of tankers to Britain and U. S. S. R.; prohibition of exports of petroleum products to Japan; assumption of coordination of the aviation-gasoline industry by the Office of Petroleum Coordinator; signing by the State Department of an agreement with Mexico providing a plan for settlement of the controversy over expropriation of United States-owned oil properties in Mexico; coordination of oil production and allocation of production rates for each State by the Office of Petroleum Coordinator; and prohibition by the Office of Petroleum Coordinator of the drilling of more than 1 well to 40 acres, to be enforced by withholding priorities for drilling equipment from violators.

The action that affected the oil industry most was the establishment of the Office of Petroleum Coordinator by order of the President on May 28, 1941, with Harold L. Ickes, Secretary of the Interior, as Coordinator. The Coordinator is empowered to obtain information regarding the needs and availability of petroleum and petroleum products and to recommend action that will insure maintenance of a supply thereof. The country is divided into five districts, and each district has four industry advisory committees dealing with production, refining, transportation, and marketing. These committees are appointed by the Coordinator from nominees selected by the industry and have contact with the Coordinator through a general committee composed of the chairmen of each committee, as well as the general chairman of each district.

Toward the end of the year, the Coordinator organized the Petroleum Industry Council for National Defense, later called the Petroleum Industry War Council. This council comprises 66 members selected from the petroleum industry, and the 25 men on the general committee described above are ex-officio members. The functions of the Council are to mobilize most effectively the resources and abilities of the petroleum industry; to advise the Petroleum Coordinator with respect to the petroleum industry; and to carry into effect measures recommended by the Coordinator as essential to national defense.

The Petroleum Coordinator has no power to enforce his decisions; they must be executed through voluntary cooperation of the industry or through other agencies with enforcement power, such as the War Production Board, acting on the recommendations of the Coordinator. The petroleum industry, through its Petroleum Industry War Council and its general and district committees, enjoys unusual facilities for contact with the Government.

PRORATION

Any doubt of a State's right to prorate oil production was removed when the Supreme Court early in the year upheld the Texas system of proration.

The Interstate Oil Compact Commission gained strength during the year when, in addition to extension of the Compact Commission Act 2 years by Congress, four more States joined—Arkansas, Louisiana, New York, and Pennsylvania. These, added to the older member States—Colorado, Illinois, Kansas, Michigan, New Mexico, Oklahoma, and Texas—make a total of 11 States now in the Commission.

Late in the year the Office of Petroleum Coordinator assumed the function of designating the quantity of crude oil to be produced and allocating the rates of production for each State. One of the most important features in this connection was the new production plan for California put into effect on January 1, 1942. This is the first regulatory measure for California, as heretofore proration in that State has taken the form of voluntary curtailment. Two acts to regulate oil and gas production, passed by the legislature, were defeated by referendum.

CRUDE PETROLEUM

SUPPLY AND DEMAND

The total demand for crude petroleum was approximately 1,474 million barrels in 1941—a gain of 101 million barrels or over 7 percent above that in the previous year. The domestic production of 1,404 million barrels was supplemented by a decline of almost 19 million barrels in all crude stocks compared with an increase of over 23 million in crude stocks in 1940. Imports of crude increased and exports declined, but total figures are not available for publication. Total runs to stills rose from 1,294 million barrels in 1940 to 1,409 million in 1941—a gain of 115 million barrels (8.9 percent).

[4] Exclusive of heavy crude in California.

PRODUCTION

Despite declines in exports of petroleum and its products in 1941, an increase of 51 million barrels in production of crude oil was required to supply the demand, even with a substantial reduction in stocks. Daily average production rose from 3,569,000 barrels in January (as shown in fig. 2), crossed the 4-million mark in October, and reached an average of 4,139,000 in December. Total production was 1,404,182,000 barrels compared with 1,353,214,000 in 1940.

The gain of 17,122,000 barrels in Kansas was the greatest of any State. Production in Texas increased 14,375,000 barrels and that in Louisiana 12,324,000. Illinois and Michigan declined 13,509,000 and 3,392,000 barrels, respectively, although the trend was upward in both States at the end of the year. The relative rank of the three highest producing States—Texas, California, and Oklahoma—declined further, so that in 1941 they supplied only 63.6 percent of the oil produced compared with 64.5 percent in 1940 (see fig. 3).

East Texas maintained its lead as the greatest producing field. The precipitous drop in output from the Salem (Ill.) field from 71 million barrels in 1940 to 30 million in 1941 reduced its rank from second to fourth. It was succeeded by the declining Oklahoma City field, whereas the Wilmington (Calif.) field, with a slight gain in production, ranked third.

[4] Revised.

Arkansas.—A small gain (principally attributable to the younger fields, as the recoveries from the older ones were generally less than in the previous year)—552,000 barrels—raised the 1941 production to 26,327,000 barrels. The chief exception was the Urbana field, where more than doubling the number of wells in the past 2 years has increased the production from 381,000 barrels in 1939 to 837,000 in 1941. Production in the Atlanta field rose 292,000 barrels to 1,013,000, and the McKamie field—the largest gas reserve in the State—yielded 891,000 barrels of distillate.

Drilling operations continued to decline, as only 95 oil wells were completed in 1941 compared with 114 in 1940. The new Mount Holly field was the only oil field discovered during the year.

California.—Production in California gained 6,382,000 barrels in 1941 and reached 230,263,000 barrels, or an average of 631,000 daily. Although this is 19,000 barrels above the 1940 average, it is still far below the 1938 figure. About 11,000 barrels of this increase in the daily average is attributable to the reopening of heavy-oil wells—some of them closed for years—whose product is now in demand for naval and industrial fuel. That this developed during the latter half of the

year is indicated by the daily average production of 85,800 barrels of unrefinable crude for this period compared with 63,300 barrels for the first half of the year—the same as for 1940.

Nine hundred and twenty oil wells were completed in 1941 compared with 859 in 1940. The average initial daily production was 712

[2] Includes Tupman

barrels compared with 891 in 1940. Dry holes drilled numbered 179—23 more than in 1940.

Production gains were confined to the San Joaquin Valley and Coastal districts; the former increased 6,529,000 barrels and the latter 3,666,000. Production in the Los Angeles Basin declined 3,813,000

barrels. The Wilmington field still led, with an output of 30,672,000 barrels, whereas Kettleman Hills (which in 1940 yielded second place to Midway-Sunset) was exceeded also in 1941 by Long Beach and Coalinga, the latter rising from 9,916,000 barrels in 1940 to 14,224,000 in 1941 compared with a production of only 3,898,000 barrels in 1938.

Ten new fields were discovered in California in 1941, 8 of them in the San Joaquin Valley. The most important was the Raisin City, not because of its production but because it established the presence of oil north of Coalinga, a territory many theretofore had considered barren. Discoveries of the Helm and Riverdale fields later in the year expanded the oil possibilities in this area.

Colorado.—Production in Colorado increased from 1,626,000 barrels in 1940 to 1,875,000 in 1941. Chiefly responsible for this was the Wilson Creek field, where discovery of oil in the Sundance formation raised the output from 237,000 barrels in 1940 to 453,000 in 1941. The Hiawatha gas field, where oil was discovered in June 1940, increased production 116,000 barrels, bringing the yield for this field to 191,000 in 1941.

Only 16 wells were completed during the year, 6 of them small ones in the Rangely field and 3 of them in the Wilson Creek field (the latter averaging 439 barrels a day initial production).

Illinois.—Production in Illinois declined from 147,647,000 barrels in 1940 to 134,138,000 in 1941. New discoveries brought the daily average output from 323,900 barrels in February to 423,100 in September, from which it dropped to 397,800 in December—slightly lower than the average for 1940. Federal restrictions on drilling and production, however, indicated that the production in Illinois would be even lower in 1942.

Outstanding in decreased yield was the big Salem field, whose 58-percent decline slashed its output from 70,734,000 barrels in 1940 to 29,539,000 in 1941. Other fields reporting notable declines were the Centralia field, which dropped from 10,642,000 barrels to 3,564,000, and the Louden field, which dropped from 26,596,000 barrels to 22,918,000.

New oil wells numbered 2,730, or 319 less than in 1940, and the initial daily average dropped from 620 barrels in 1940 to 277 in 1941 compared with 285 in 1939.

The Johnsonville field was the outstanding new discovery. The first well in this field was brought in during July, and during the half year 217 oil wells were completed with an average initial daily pro-

duction of 920 barrels. The original production in this field was found in the McClosky sand, but deeper drilling proved the Aux Vases formation productive. The Benton field, discovered in January, produced 5,769,000 barrels from 222 wells completed, with an average daily initial of 285 barrels. It is a significant fact that production in this field is from the Tar Springs formation, which heretofore has been the source of only small wells. The importance of the Benton discovery spurred search for the Tar Springs sand in other parts of the State and resulted in several other discoveries. Although a test of the Devonian lime in the Louden field proved oil in that formation, the quantity was disappointing. The most active field was the New Harmony in White County, where 439 oil wells were completed with an average initial daily production of 161 barrels. Worthy of mention among the new discoveries are the Rising Sun, East Centerville, and Roland fields, also in White County, and the Rural Hill and Woodlawn fields, in Hamilton and Jefferson Counties, respectively.

The Aux Vases sand, prominent in the Salem field, furnished much of the new production in 1941. As mentioned above, it is one of the sources of production in the Johnsonville field, and deeper drilling in the Dale and Hoodville fields to this formation raised the output from 314,000 barrels in 1940 to 2,483,000 in 1941 in the former and from 353,000 to 3,712,000 in the latter. These successes led to other discoveries, as yet too new to be evaluated.

Indiana.—New discoveries in Indiana raised the production from 4,978,000 barrels in 1940 to 6,634,000 in 1941. More than half of the output, however, came from the Griffin field, and it was the scene of the greatest drilling activity.

Two hundred and sixty-two oil wells were completed averaging 109 barrels initial daily production compared with 231 completions and 139 barrels initial production in 1940; 128 of the completions were in the Griffin field and 25 in the New Harmony.

[1] Subject to revision.

Kansas.—Production in Kansas established a new record in 1941, when a 26-percent gain over 1940 raised the output to 83,261,000 barrels compared with the previous peak of 70,761,000 barrels in 1937. The increased output was in response to a greater demand to replace declining production in Illinois and Oklahoma and was made possible by the expansion of pipe-line facilities in Kansas. Production

Production of crude petroleum in Kansas, 1937–41, by counties and selected fields [1]

[1] Oil and Gas Journal.

in Kansas has been restricted because of inadequate transportation facilities; but with the pressure of demand many pipe lines have been looped to enlarge their capacity, and new lines have been installed to fields not having that type of transportation in the past.

There were 1,420 wells drilled with an average initial daily production of 1,032 barrels compared with 1,410 wells drilled in 1940 with an average initial of 460 barrels. The number of wells increased from 20,655 to 21,838, according to the Oil and Gas Journal.

Reno and Stafford Counties led in development during 1941. Success of 80 wells completed in the Zenith field with an average initial daily production of 1,510 barrels spurred further exploration, leading to the discovery in July of the Peace Creek field, where 18 wells were completed with an average initial daily production of 2,830 barrels. The productive area was increased further by discovery of the Hendrickson pool in December. Production in these fields is from the Viola lime and overlying Misener sand. Discovery of oil in August in far western Kearny County in a stray Pennsylvanian sand, distant from any other production, was one of the most significant developments of the year because of the new possibilities it revealed.

Kentucky.—Crude-oil production in Kentucky continued to decline, dropping to 4,762,000 barrels in 1941 from 5,188,000 in 1940. Completions numbered 233 compared with 224 in 1940. The only development of interest in the State was the discovery of the Ordovician formation at Sinking Creek which resulted in some leasing activity and hopes for future production.

Production of crude petroleum in Kentucky, 1937–41, by months

[1] Subject to revision.

Louisiana.—Kansas and Texas were the only States where production increased more than it did in Louisiana. The gain of 12,324,000 barrels—12 percent—raised the output to 115,908,000 barrels compared with 103,584,000 in 1940.

Despite a year of drilling activity, production in northern Louisiana increased only from 24,406,000 barrels in 1940 to 25,354,000 in 1941. The Rodessa field continued to decline but retained first place, and the Olla field, discovered in 1940, crossed the 4-million barrel mark to rank as second-largest in the northern part of the State. The Lisbon field, which ranked third in 1938 with over 3 million barrels production, dropped to less than 1 million in 1941.

The Cotton Valley field, ranking second in this area in 1940 but displaced by Olla in 1941, did not decline as the statistics seem to indicate. After completion of a large recycling plant in this field in July 1941 the condensate formerly included with crude-oil production was segregated into the individual products. In addition to the 3,459,000 barrels of crude oil produced from this field in 1941, con-

densate and natural-gasoline output totaled 2,186,000 barrels and butanes plus other products, 109,000 barrels; in 1940, 211,000 barrels of natural gasoline and condensate were produced separately, and crude-oil output, including condensate, totaled 5,189,000 barrels.

[2] Includes crude oil consumed on leases and net change in stocks held on leases for entire district.
[3] Includes Hemphill and Trout Creek.
[4] Includes Little Creek and Summerville.

There were 467 oil-well completions in northern Louisiana in 1941 with an average initial daily production of 106 barrels compared with 448 completions with an average initial of 114 barrels in 1940. Greatest activity was in the Caddo field, where 163 wells were completed with an initial daily production of 57 barrels. Next greatest activity was in the 1940 discoveries—the Olla and Nebo fields producing from the Eocene Wilcox sands in La Salle Parish with 92 completions

averaging 137 barrels daily in the former and 71 completions averaging 153 barrels daily in the latter. Further drilling in these sands discovered new fields the latter part of the year at a deeper level. The Wilcox trend is developing into one of the most important sources of production in northern Louisiana as well as upper Gulf Coast Texas. An important discovery late in the year was production in the Pettit lime in the old Haynesville pool in Claiborne Parish.

Production in the Louisiana Gulf Coast district rose from 79,178,000 barrels in 1940 to 90,554,000 in 1941. This gain was widespread, and the output in 6 parishes increased more than 1 million barrels each. The greatest advance was in Plaquemines Parish, where production rose from 5,162,000 barrels in 1940 to 8,788,000 in 1941. The average initial daily production from the 67 wells drilled in this parish was 361 barrels. Grand Bay and West Bay fields were 1941 discoveries in Plaquemines Parish, with 12 completions having an initial daily production of 313 barrels in the former and 13 completions having an initial daily production of 386 barrels in the latter. Ville Platte, in Evangeline Parish, had the greatest increase of any one field, the output of 6,119,000 barrels compared with 4,493,000 in 1940 identifying it as the largest field in the State. The average initial daily production for the 65 wells drilled in this field was 230 barrels. Production from this field comes principally from the Wilcox trend. Jennings, highest producing pool in 1940, dropped to second place in 1941, being exceeded by Ville Platte only.

There were 614 oil-well completions in the Louisiana Gulf Coast district, with an average initial daily production of 252 barrels compared with 741 completions with an average initial of 307 barrels in 1940. Sixteen new fields were found; the most important were Bayou Sale in St. Mary Parish and St. Gabriel in Iberville Parish.

Michigan.—The decline in production from the large Michigan fields was so precipitous that despite many new discoveries the output dropped from 19,753,000 barrels in 1940 to 16,361,000 in 1941. Production in the Redding field dropped from 3,986,000 barrels to 1,749,000, and in the Walker field from 4,218,000 barrels to 1,292,000, in addition to declines of sizable proportions in many other fields. New discoveries during the year, however, reversed the trend, so that December production was almost half again as much as that of January, giving the prospect that the output in 1942 probably would exceed that of 1941.

Four hundred and thirty-three oil wells were completed in 1941 with an average initial daily production of 1,131 barrels, compared with 536 completions with an average initial of only 215 barrels in 1940.

The Reed City field, discovered in Osceola County late in 1940, had the greatest activity when deep drilling about the middle of the year revealed a large pool in the Monroe and Traverse formations. There were 113 wells completed in this field, with an average initial daily production of 3,511 barrels, and the pool supplied 2,754,000 barrels of the State production.

Oil was discovered in the Headquarters pool, Roscommon County, in June, and during the rest of the year 12 wells were completed with an average initial daily production of 3,695 barrels. Notwithstanding 77 completions in Allegan County, production dropped from 2,710,000 barrels in 1940 to 1,440,000 in 1941. Twenty-four completions in Arenac County caused a gain in production from the

Adams pool from 313,000 barrels in 1940 to 1,118,000 in 1941. The Winterfield pool, brought in as a gas field in Clare County in 1940, yielded 1,101,000 barrels of oil in 1941. The 30 wells drilled in this county had an average initial daily production of 424 barrels. Although there were numerous other discoveries, they seemed of minor importance.

Production of crude petroleum in Michigan, 1937–41, by fields [1]

[1] Data from Department of Conservation, Michigan.

Mississippi.—Youngest except one among the country's oil-producing States, at the end of 1941 Mississippi had taken the rank of ninth-largest, and the rapid expansion of its output indicated that it would soon reach seventh place. Total production for 1941 was 15,314,000 barrels compared with 4,400,000 in 1940. Most of this came from the Tinsley field, although the Pickens field was the source of a small amount.

There were 219 oil-well completions averaging 589 barrels initial daily production compared with 107 completions averaging 554 barrels initial production in 1940. All but two of these wells were drilled on the Tinsley dome, extending it and discovering production in newer zones. Seven producing zones have now been established in the field. The other two completions were discovery wells in new fields. One in Sharkey County, discovered in October, seems of little importance; but the other, discovered in Madison County in December, had a large initial daily production and caused immediate activity in the area.

Production of crude petroleum in Mississippi, 1939–41, by months

[Thousands of barrels]

Montana.—Production in Montana continued to increase, rising from 6,728,000 barrels in 1940 to 7,526,000 in 1941. Although production for the entire State increased 798,000 barrels, that of the Cut Bank field rose 929,000 barrels to total 5,020,000, representing 67 percent of Montana's total. Despite active drilling and a new discovery on the west side, production from the Kevin-Sunburst field declined from 1,923,000 barrels to 1,753,000. All drilling activity

except one well completed in the Frannie field was concentrated in the Cut Bank and Kevin-Sunburst fields. Extension of the west and south sides of the Cut Bank field brought in 111 new wells with an average initial daily production of 177 barrels, and 48 wells were completed in the Kevin-Sunburst field with an average initial of 111 barrels.

[3] Includes crude oil consumed on leases and net change in stocks held on leases for entire State.

Nebraska.—Crude-oil production in Nebraska became significant in 1941, when it amounted to 1,636,000 barrels compared with 276,000 in 1940. Most of this oil came from the Falls City pool. Completions numbered 38, with an average initial daily production of 360 barrels.

New Mexico.—The 39,369,000 barrels produced in New Mexico in 1941 was only a slight increase over the 1940 yield. The declining Monument and Eunice fields still maintained the lead, both having gained slightly over their 1940 output. Identified with these fields, the Arrowhead field, discovered in 1940, increased its production over one-half million barrels to 1,429,000. The south Maljamar field, however, increased from 760,000 barrels in 1940 to 1,651,000 in 1941 for the largest gain of any field. There were 63 completions in this field, with an average initial daily production of 361 barrels. Production from the Loco Hills field increased almost 350,000 barrels.

Oil-well completions numbered 209, with an average initial daily production of 221 barrels in 1941 compared with 479 completions with an average initial production of 345 barrels in 1940.

New York.—Production in New York increased from 4,999,000 barrels in 1940 to 5,185,000 in 1941, the largest output since 1937. Production was encouraged by the strong demand for lubricating oil, which in June took the price of Bradford crude to $2.75 per barrel—the "ceiling" imposed for this crude by the Price Administrator.

According to the Oil Weekly, new completions numbered 674, with an average initial daily production of 7 barrels. Repressuring operations were active, and 441 wells were drilled for water input.

Ohio.—Production in Ohio totaled 3,340,000 barrels in 1941 compared with 3,159,000 in 1940. Oil-well completions numbered 419, with an initial daily production of 27 barrels, compared with 323 completions in 1940.

Greatest activity was in Medina County, where 132 small wells were completed, but the principal development was in Perry County, with 67 new wells. Of these, 45 with an average initial daily production of 152 barrels from the Clinton sand extended the Clayton pool. Eight wells were drilled in the northwestern part of the county, with an average initial daily production of 120 barrels.

Production of crude petroleum in Ohio, 1937–41, by months

Oklahoma.—Notwithstanding great drilling activity, production in Oklahoma continued to decline and dropped to 154,759,000 barrels in 1941 compared with 156,164,000 in 1940 and 228,839,000 in 1937. Decreases in the Oklahoma City field output from 35,970,000 barrels in 1940 to 32,184,000 in 1941, and in the Seminole field from 26,989,000 barrels to 23,687,000, along with losses in smaller fields, more than offset the yield from new wells. The Fitts field, which produced more than Seminole in 1937, was down to 4,223,000 barrels in 1941.

Completions in 1941 totaled 1,099, with an average initial daily production of 226 barrels compared with 1,011 wells with an average initial of 204 barrels in 1940. The most important discovery was the Apache field in Caddo County in June, where the seven wells drilled

had an average initial daily production of 4,012 barrels from the Simpson sand. Most of the yield increases were in fields discovered before 1941. The Hewitt field, which has been producing for several years, had the greatest activity, as 119 wells were completed, mostly in the first half of the year. Their average initial daily production was 294 barrels, and the output in this field increased from 1,778,000 barrels in 1940 to 4,860,000 in 1941. Production in the Cumberland field increased from 393,000 barrels in the discovery year 1940 to 2,543,000 barrels in 1941. Completions in this field were 31, with an average initial daily production of 266 barrels. New completions also resulted in increased production in the Cement and Dill fields.

[1] Oil and Gas Journal.

Pennsylvania. Despite heavy demand, crude-oil production slumped from 17,353,000 barrels in 1940 to 16,750,000 in 1941. The trend, however, was definitely upward the last 4 months of the year, as the output for this period was 6 percent higher than for the same period in 1940. Most of the drilling was in the Bradford district, where 1,540 wells were drilled with an average initial daily production of 1.2 barrels.

Consideration of intensive recovery methods in Pennsylvania has brought interest in horizontal wells in addition to the established practice of repressuring wells. Water-input wells drilled for this purpose numbered 1,675 in 1941.

[1] Subject to revision.

Texas.—Texas production of 507,584,000 barrels was the greatest since 1937 and represented 14,375,000 barrels more than the 1940 output. The only districts to show material gains were the Gulf Coast and West Texas, and the greatest loss was in the declining East Texas, although it maintained its place as the greatest field in the world. Development of the Wilcox trend in the upper Gulf Coast district and of deeper sands in West Texas is responsible for the increases. In all, 7,262 oil wells were completed in 1941, with an average initial daily production of 373 barrels, compared with 6,632 completions with an average of 486 barrels in 1940.

Production in the Gulf Coast district increased from 122,166,000 barrels in 1940 to 135,139,000 in 1941, owing principally to development of the Wilcox trend in the upper Gulf Coast area. Although oil was discovered several years ago in the Eocene Wilcox Sand, it was not until 1939 that active development began, and the rewards have come in 1940 and 1941.

The Conroe field gained 2,327,000 barrels, maintaining its place as the largest producer in the Texas Gulf Coast field with a total output of 11,630,000 barrels. Hastings, with a gain of 2,202,000 barrels, produced 7,623,000 barrels, but Saxet-Saxet Heights, displaced by Hastings, dropped from 5,634,000 barrels in 1940 to 4,578,000 in 1941. Development of the Marginulina-Frio sands in Jackson County resulted in large gains in the Lolita and West Ranch fields.

There were 1,353 oil wells completed in the Gulf Coast area, with an average initial daily production of 196 barrels, compared with 1,072 completions having an initial production of 276 barrels in 1940. Greatest activity was in the West Ranch and Lolita fields, where 133 and 113 wells were completed with an average initial daily production of 243 and 196 barrels, respectively. Wells with the largest average initial daily production were in the Tom O'Connor field—19 with 548 barrels average; Fannett—16 with 539 barrels average; Anahuac—23 with 499 barrels average; and West Columbia—26 with 328 barrels average.

Production in West Texas increased from 84,494,000 barrels in 1940 to 92,907,000 in 1941. The Slaughter district had the largest gain, and Wasson and Cowden, the largest producing districts, ranked next in reverse order. There were 2,123 oil wells completed in West Texas with an average initial daily production of 841 barrels compared with 1,717 completions in 1940 averaging 891 barrels. Output from the Slaughter district, northernmost field in West Texas and the most active drilling center in the Nation in 1941, rose from 841,000 barrels in 1940 to 4,612,000 in 1941. Oil-well completions numbered 634, with an average initial daily production of 1,051 barrels. There were 284 wells drilled in the Wasson district, largest producing district in West Texas, averaging 692 barrels initial production. The North

Cowden, Foster, and Johnson fields in the Cowden district all showed large increases, and 120 new wells in Seminole almost tripled the output from that field.

Despite great drilling activity, increased production from several fields, and the discovery of a new large field, yield from the eastern part of Texas dropped from 168,919,000 barrels in 1940 to 161,634,000 in 1941, owing principally to declines in the East Texas, Van, and Rodessa fields, whereas increases in Long Lake, Cayuga, and Talco, plus the output from the new Hawkins field, helped to stem the drop. In all, 798 wells were completed with an average initial daily production of 160 barrels.

The Hawkins field, discovered in the last days of 1940, produced 1,432,000 barrels of oil in 1941 from the 226 wells completed during the year, with an average initial daily production of 348 barrels.

Although there was a great amount of drilling activity in North Texas in 1941, production was little changed from that of 1940. There were 2,456 wells drilled of which 1,593 were oil completions. A number of new pools were discovered, and new production was found in deeper formations, particularly the Ellenburger. There were 268 completions to this formation in the K. M. A. field, with an average initial daily production of 326 barrels. Ninety-five wells completed in the Hull-Silk field raised its production more than a million barrels—the only field in North Texas to have a large gain.

Although 648 wells were completed in the Panhandle, no unusual developments or new discoveries were made. There was a small gain in production.

[1] Subject to revision.
[2] Included under "Other Gulf Coast."
[3] Includes crude oil consumed on leases and net change in stocks held on leases for entire district.
[4] Joiner, Kilgore, Lathrop, and other pools in Cherokee, Gregg, Rusk, Smith, and Upshur Counties.
[5] Includes other fields in Falls, Freestone, Limestone, and Navarro Counties.
[6] Includes the fields in and between Wilbarger, Wichita, Clay, Montague, and Cooke Counties on the north and Runnels, Coleman, Brown, and Comanche Counties on the south.
[7] Includes crude oil consumed on leases and net change in stocks held on leases for East Texas, exclusive of East Texas proper, Central, North, and South Texas.
[8] Carson, Gray, Hutchinson, Moore, Potter, and Wheeler Counties.
[9] Includes fields in Duval, Hidalgo, Jim Hogg, Jim Wells, Starr, Webb, and Zapata Counties.

West Virginia.—The output of 3,433,000 barrels in 1941 was slightly less than the 3,444,000 barrels produced in 1940, but the trend was upward, as production in the last 4 months of 1941 was 2 percent higher than that for 1940.

There were 115 new wells drilled, with an average initial daily production of 15 barrels.

Production of crude petroleum in West Virginia, 1937–41, by months

Wyoming.—Production rose from 25,711,000 barrels in 1940 to 29,694,000 in 1941. The greatest gain was in the Lost Soldier field, where the output rose from 2,070,000 barrels in 1940 to 4,745,000 in 1941. Seven wells were completed in this field, with an average initial daily production of 784 barrels. A 63-percent gain raised production in the Grass Creek field from 718,000 barrels to 1,171,000, although no new completions were reported.

There were 123 oil wells completed during 1941 but no new fields were found. Drilling was most active in Lance Creek, where 26 wells were brought in with an average initial daily production of 608 barrels, notwithstanding which production dropped from 9,121,000 barrels to 8,838,000. Production in La Barge field rose from 585,000 barrels to 769,000, in consequence of 16 completions; 13 wells were completed in the Osage field and 11 in Oregon Basin. Production in the latter field rose from 2,725,000 barrels to 3,197,000.

WELLS

The lethargy in drilling that set in during June 1940 continued well into 1941 and oil-well completions in March 1941 were 382 less than in March 1940. However, an increase of 335 completions in July 1941 over those for June indicated the effect of the price increases earlier in the year and prompted new activity that raised the total of oil wells completed during the year to 19,195—70 more than in 1940 (see fig. 4). The total for the year was exceeded only in 1920 and 1937.

Total completions in 1941, including oil and gas wells and dry holes, were almost 1,000 more than in 1940—29,070 compared with 28,124. Industrial needs for gas resulted in an increase of 608 gas-well completions to 2,990, and dry holes drilled increased 268 to total 6,885. The proportion of oil wells to total completions dropped about 2 percent; that of gas wells increased about 2 percent; and that of dry wells remained virtually the same.

The 1,054 dry wells drilled in North Central Texas—37 percent of all completions in that area—indicate the great amount of wildcat activity in this area. Illinois had the next largest number—890—but they represented only 25 percent of total completions. Michigan's 419 dry wells, representing 45 percent of the total completions, was the largest proportion, and Ohio's 502 dry wells represented 30 percent of the completions.

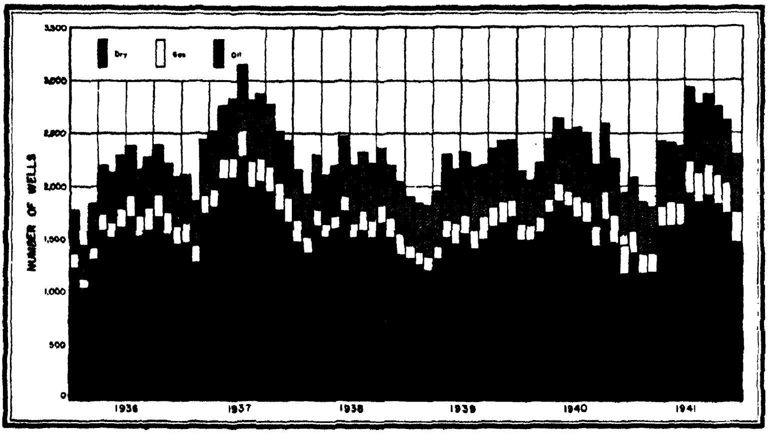

FIGURE 4.—Wells drilled in the United States, 1936–41, by months.

Elimination of excessive drilling was designed by General Preference Order M–68, issued by the Office of the Petroleum Coordinator in December, providing for easy acquisition of drilling and operating material and supplies by operators who conform to that office's spacing pattern—one well to each 40 acres. Further search for oil was encouraged by excluding wells drilled for exploratory operations from any restrictions. As this order was issued near the end of the year, it had no influence on 1941 completions, but it is expected to curtail drilling operations severely in 1942.

STOCKS

Total crude-oil stocks declined about 19 million barrels in 1941 compared with an increase of over 23 million barrels in 1940. An increase of about 2 million barrels in the first quarter was followed by declines of over 8 million barrels in the second quarter and a further decline of 13 million barrels in the third quarter. These decreases were incident to a more rapid increase than had been anticipated in the demand for all oils. By the fourth quarter, production had been increased to a peak level, and crude stocks showed a slight increase. Total stocks of crude oil amounted to 257,063,000 barrels on December 31, 1941, compared with 275,985,000 barrels on December 31, 1940. Stocks of refinable grades declined by over 17 million barrels, and stocks of California heavy crude decreased less than 2 million.

Stocks of crude petroleum, natural gasoline, and refined products in the United States at end of year, 1937–41

[1] Subject to revision
[2] For comparison with succeeding year.
[3] Includes also equivalents for wax, coke, and asphalt in barrels

The data on stocks of crude oil by States of origin for 1941 show that the largest declines were 11.7 million barrels for Oklahoma, 2.0 million for California crude of all grades, 1.9 million for Illinois, 1.6 million for Texas, 1.0 million for Kansas, and 0.9 million for Arkansas. Stocks of Appalachian crude decreased 0.7 million barrels and stocks of foreign crude about 0.6 million. The largest increases in crude stocks were 1.7 million barrels for Mississippi, 0.7 million for Michigan, and 0.4 million for Montana.

The demand for domestic crude was almost 7 percent greater in 1941 than in 1940, whereas crude production increased less than 4 percent. This differential is accounted for by the addition to production of 18.3 million barrels taken from all stocks of domestic origin in computing demand for 1941, whereas 22.9 million barrels of the 1940 production went into storage.

Stocks of refinable crude petroleum in the United States in 1941, by States of location and origin and by months [1]

[3] Revised figures for 1940 (Minerals Yearbook, Review of 1940, p. 962) are as follows (thousands of barrels): Producers' stocks—January 31, 12,310; February 28, 12,034; March 31, 12,290; April 30, 12,207; May 31, 12,105; June 30, 12,290; July 31, 11,886; August 31, 12,128; September 30, 11,903; October 31, 11,819; November 30, 11,778; December 31, 11,535.
[4] For comparison with succeeding year.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—Crude runs to stills again exceeded all previous records in 1941, with a total of 1,409 million barrels—an increase of 115 million (8.9 percent) over 1940. Foreign crude runs gained 9 million barrels, and domestic crude runs increased 106 million.

Refinery operations exceeded demand, as indicated by an increase of about 9 million barrels in stocks of refined oils. As there was a further decline in the total exports of refined oils and an increase in the imports of refined products, the gain in total demand for refined products was due entirely to an increase in domestic demand.

There were substantial increases in refinery operations in all districts in 1941. Crude runs increased about 25 million barrels over 1940 in both the Indiana-Illinois-Kentucky and the Texas Gulf Coast districts. East Coast runs were about 13 million barrels greater, and the Oklahoma-Kansas-Missouri and the California districts each showed a gain of over 12 million. Runs in the Louisiana Gulf Coast district rose 9 million barrels. Increases of about 5 million barrels occurred in the Appalachian district and in the Texas Inland and Arkansas-Louisiana Inland districts, and the Rocky Mountain district gained over 3 million barrels.

Distribution.—Receipts of domestic and foreign crude petroleum at refineries in the United States totaled 1,299 million barrels in 1940 and 1,410 million in 1941. In 1941 receipts of foreign crude at refineries were about 51 million barrels or about 3.6 percent of the total compared with 3.3 percent in 1940; interstate receipts of domestic crude were 544 million barrels or 38.6 percent compared with 37.5 percent in 1940; and intrastate receipts were 815 million barrels or 57.8 percent compared with 59.2 percent in 1940.

Refinery receipts of crude in 1941, by methods of transportation, indicated that 73.9 percent of the total was delivered by pipe lines compared with 72.4 percent in 1940; that 22.7 percent was delivered by boat compared with 24.7 percent in 1940; and that 3.4 percent was delivered by tank car and truck compared with 2.9 percent in 1940.

The total demand for domestic crude petroleum in 1941 amounted to 1,422.5 million barrels—a gain of about 92 million (almost 7 percent) over 1940. Domestic crude run to stills was 1,358 million barrels, and the remainder (about 64 million) represented exports, crude used for fuel, and losses.

The most important changes in market demand by States of origin (computed from production and changes in crude stocks by origin) in 1941 compared with 1940 were increases of about 29 million barrels for Texas, 20 million for Kansas, 15 million for Louisiana, 13 million for Oklahoma, 10 million for Mississippi, and 7 million for California. The largest declines in crude demand were about 9 million barrels for Illinois and 5 million for Michigan.

The total demand for Texas crude rose from about 480 million barrels in 1940 to 509 million in 1941—an increase of about 6 percent. In 1941 about 344 million barrels of Texas crude were delivered to refineries within the State and 146 million barrels to refineries in other States; 108 million went to the East Coast district, 23 million to the Indiana-Illinois-Kentucky district, 11 million to refineries in Louisiana, and 3 million to the Oklahoma-Kansas-Missouri district. In addition

Runs to stills of crude petroleum in the United States in 1941, by districts and months [1]

[1] Subject to revision.

to crude, a large volume of products from Texas refineries is shipped to East Coast markets, so that any interruption in tanker transport seriously affects the market demand for Texas crude.

The demand for California crude increased from 225 million barrels in 1940 to 232 million in 1941—about 3.2 percent. The increase in Pacific coast demand for California oil offset the effects of the termination of exports to Japan in August and the elimination of shipments to the East coast. The production of crude was about 230 million barrels, and this was supplemented by a decline of about 2 million barrels in crude stocks. Only about 0.1 million barrels of crude were sent to the East coast in 1941. Practically all of the crude output was refined in the State, except for relatively small exports to Japan and western Canada.

Demand for crude petroleum by States of origin, 1938–41

[1] Subject to revision.

The market demand for Oklahoma crude increased from 153 million barrels in 1940 to 166 million in 1941. In 1941 the production of 155 million barrels was supplemented by withdrawal of over 11 million barrels from stocks. Production has been declining steadily since 1937. Deliveries to refineries within the State amounted to 56 million barrels in 1941. About 16 million barrels were delivered to refineries in Kansas and Missouri, 69 million barrels to Indiana-Illinois-Kentucky refineries, and 14 million to East coast refineries.

The rapid rise in the demand for Illinois crude—from 23 million barrels in 1938 to a peak of almost 145 million in 1940—and then a drop to 136 million in 1941 has materially changed the trends in demand for other States. It has supplied much of the increased crude required in the refineries of the Indiana-Illinois-Kentucky district. Output exceeded demand from 1938 to 1940, resulting in an increase of about 10 million barrels in stocks by States of origin. In 1941, the production of about 134 million barrels was supplemented by a stock

Daily average demand for crude petroleum by States of origin, in 1941,[1] by months

[2] Missouri and Tennessee.

decrease of almost 2 million. Production reached a peak of 423,000 barrels daily in October 1941 and declined to about 292,000 barrels daily by May 1942. In 1941, intrastate deliveries of Illinois crude amounted to about 41 million barrels and represented almost half the crude refined in the State. Deliveries to refineries in other States totaled about 80 million barrels, of which 46 million went to other States included in the Indiana-Illinois-Kentucky refining district, 24 million to the Appalachian district, and 10 million to the East Coast district.

The demand for Louisiana crude has been steadily increasing and rose from 101 million barrels in 1940 to over 116 million in 1941. Deliveries to refineries within the State amounted to 39 million barrels in 1941. The principal outside markets are the Texas Gulf and East Coast refinery districts, which received 47 million and 21 million barrels, respectively, in 1941.

The demand for Kansas crude rose to 84 million barrels in 1941—an increase of 20 million over 1940. Demand was about evenly divided between refineries within the State and shipments to other States. Shipments to refineries in Illinois and Indiana amounted to 32 million barrels in 1941 compared with 20 million in 1940.

The demand for New Mexico crude increased to 40 million barrels in 1941—a gain of 2 million. Less than 2 million barrels are used within the State. Deliveries to other districts in 1941 included 25 million barrels to Texas refineries, 7 million to the East Coast district, and over 5 million to Illinois.

The demand for Wyoming crude increased about 2 million barrels to total over 29 million in 1941. Intrastate deliveries amounted to about 14 million barrels, shipments to other Mountain States were about 9 million, and refineries in Indiana, Illinois, Kansas, and Missouri received over 5 million.

The demand for Arkansas crude amounted to 27 million barrels in 1941, of which 13 million barrels went to local refineries and an equal amount was sent to refineries in Louisiana. With the rapid rise in production, the demand for Mississippi crude increased 10 million barrels in 1941 to total about 14 million barrels. About half was delivered to Louisiana refineries, and the rest went to Illinois, Kentucky, and East Coast States. Declining production reduced the demand for Michigan crude to less than 16 million barrels in 1941, the major part being refined within the State.

Distribution of crude petroleum in the United States in 1941, by States [1]

PRICES AND VALUE

Record demand for products of petroleum started crude-oil prices upward early in the year (see fig. 5). Changes to the latter part of May increased the price of Bradford Pennsylvania Grade crude from \$2.15 a barrel to \$2.55; Oklahoma (36°–36.9°) crude from \$1.02 to \$1.17; Santa Fe Springs, California, (33°–33.9°) crude from \$1.14 to \$1.26, and Kettleman Hills crude from \$1.19 (on March 12) to \$1.29. Toward the end of May the Office of Price Administration and Civilian Supply called a meeting of representatives of the oil industry to request that no changes be made in the prices of petroleum or its products without first consulting that office. Postings of higher prices in the Appalachian district in August and in North Texas in November were rescinded after hearings by the Office of Price Administration and Civilian Supply. The price increase in California on May 23, which was coincident with the last increases in other parts of the country, was also rescinded but after later hearings was permitted to stand. In October crude-oil prices were ordered frozen as of October 1, pending study and further action by the Price Administrator.

REFINED PRODUCTS

Increase in defense activities during 1941 expanded the requirements from the oil industry so greatly as to tax its refining capacity. In addition to bringing record demands for all products, shifts in importance, although not in quantity, developed, which directed primary interest of the country to the production of aviation gasoline and synthetic rubber.

The future promises an even greater upset in the balance of the products of crude oil. Difficulty in getting tires, along with cessation in the production of new cars, is destined to reduce gasoline consumption to an extent that cannot yet be foreseen. The demand for residual fuel oil for needed war production, however, is increasing. Hence the industry will be presented with the necessity of curtailing the proportion of gasoline produced and at the same time raising the proportion of fuel-oil output in the face of a probability of decreased imports of heavy foreign crude. Greater reforming of gasoline seems necessary to supply at least part of those octane elements lost in the butane, the high octane straight-run naphtha, and the tetraethyl lead being diverted for aviation gasoline. The greater losses in reforming will reduce the yield of gasoline but add to its quality and at the same time supply additional gases for the production of aviation fuel.

[1] Subject to revision.
[2] Negative quantity; represents net excess of unfinished oils rerun over unfinished oils produced

Noteworthy among developments during 1941 were the controls of the oil industry brought about by the necessities of national defense. Price control was initiated on May 27, beginning with a request—later followed by a number of other requests and orders—by the Office of Price Administration and Civilian Supply that no prices be advanced without prior consultation with that office. Immediately following, on May 31, a Coordinator of Petroleum was appointed, under whose jurisdiction a number of regulations affecting the industry were promulgated. Among these were a request to the motorists in the Atlantic States to reduce their gasoline consumption by one-third, restriction of gasoline deliveries to service stations, and closing of the stations from 7 p. m. to 7 a. m., prohibiting the use of high-octane blending agents in any except aviation gasoline, and requests not to drill unnecessary wells. Exports of petroleum to Japan were prohibited August 1. The Supplies Priority and Allocation Board, organized in September, allocated steel and equipment and controlled drilling and other operations by withholding priorities.

The advent of the heavy gasoline-consuming season raised a transportation problem because the United States Government loaned a large number of tankers to Great Britain, starting with 25 sent in May. The efforts to meet the domestic situation resulting from this loan included increased movement of oil by barge and railroad and attempts to restrict consumption of gasoline for nonessential uses along the East coast. Gasoline prices were raised in this area, deliveries to dealers were cut, and service stations closed 12 hours every day. The proposal to build a pipe line from Texas to the East coast was opposed by numerous interests, and on September 9 the Supply Priorities and Allocation Board refused to allot steel for its construction. A transportation pinch was felt on the Pacific coast also, although not sufficiently to create great difficulties. The return of 25 tankers from Great Britain in the latter part of October, coinciding with the end of the heavy motoring season, solved the problem temporarily, although the Japanese declaration of war on December 7 forecast even greater transportation difficulties for the future.

The domestic demand for motor fuel increased 12 percent in 1941, the same as for residual fuel oil. Distillate fuel oil gained 8 percent, but wax—with an increase of almost 50 percent—had the greatest relative gain. The domestic demand for lubricating oil increased more than 20 percent.

Crude-oil runs to stills in 1941 totaled 1,409 million barrels compared with 1,294 million in 1940—a gain of 115 million barrels (9 percent) Foreign crude runs amounted to 51 million barrels compared with 42 million in 1940.

Refinery output of motor fuel increased 12 percent—from 597 million barrels to 671 million—the latter comprising 279 million barrels of straight-run gasoline, 344 million of cracked gasoline, and 48 million of natural gasoline.

The yield of gasoline, which had dropped from 45.0 percent of the crude oil run to stills in 1939 to 43.1 percent in 1940, recovered to 44.2 percent in 1941 (see fig. 6). Distillate fuel oil, influenced by a mild winter (see gasoline temperature index, under "Motor fuel"), receded from its 1940 record of 14.2 percent to 13.4. Of the other principal products, the yield of kerosine dropped from 5.7 to 4.2 and residual fuel oil from 24.4 to 24.3.

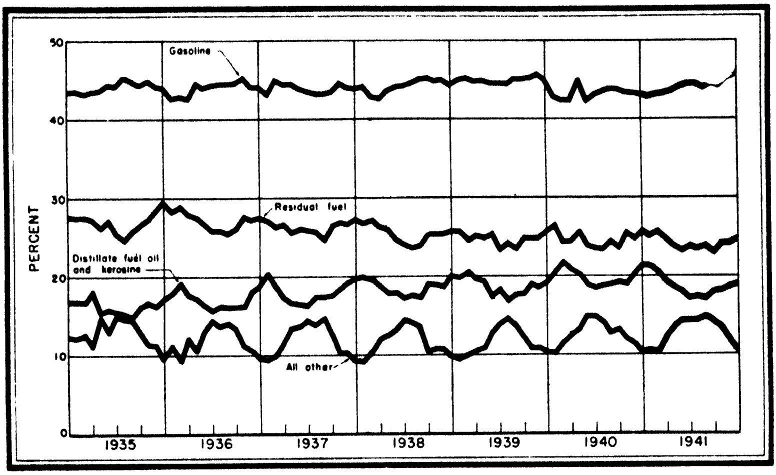

FIGURE 6.—Yields of principal petroleum products from crude oil run to stills in the United States, 1935–41, by months.

Summary of percentage yields of refined products in the United States, 1933–41

[Computed on total crude runs to stills]

[1] Subject to revision.
[2] Based upon total gasoline production minus natural gasoline used.
[3] Negative percentage; represents excess percentage rerun over percentage produced.
[4] Less than 0 1 percent.

The crude oil run of 1,409,192,000 barrels, mentioned before, represented an increase of 9 percent over the runs in 1940. These increases were distributed through all of the districts. Those in the Indiana, Illinois, Kentucky, etc., and the Texas Gulf Coast districts—25,410,000 and 25,329,000 barrels, respectively, representing relative increases of 11.3 and 7.5 percent—were greatest; however, the largest relative increases were in the Louisiana Gulf Coast and Inland Louisiana-Arkansas districts, where the gains were 20.4 and 18.5 percent, respectively.

Prices were weak during the first days of the year, and some of them sank below their low point at the close of 1940 (see fig. 7). As the year progressed, however, they gained strength, until the action of the Office of Price Administration and Civilian Supply ("Prices and value")

effectively halted advances in crude-oil prices, although those of refined products continued to rise. Refinery prices for gasoline reached their peak in July, but service-station prices advanced until December. Refinery prices of some lubricating oils reached their peak in the summer and declined thereafter, but others continued to rise until fall or near the end of the year. Most fuel-oil prices reached their peak during the summer or fall, as did also the price of wax. The request in the early part of the year that prices should not be changed became orders in October and November, when crude-oil prices were frozen as of October 1 and refined-oil prices as of November 7.

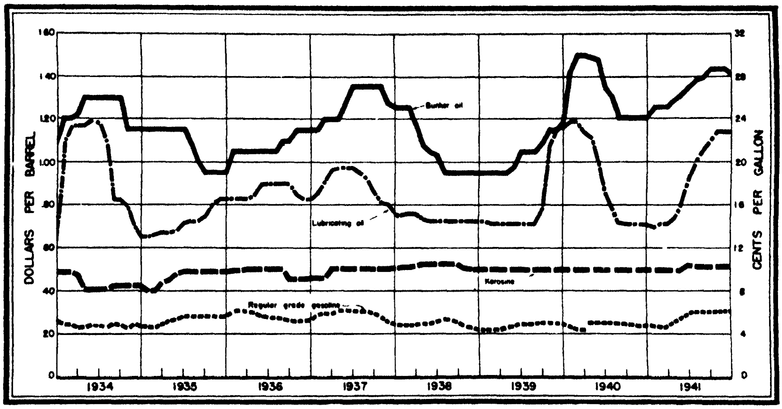

FIGURE 7.—Prices of Bunker "C" fuel oil at New York, bright stock at Oklahoma refineries, tank wagon price of kerosine at Chicago, and regular grade gasoline at refineries in Oklahoma, 1934–41, by months.

REFINERY CAPACITY

A huge program of refinery building was initiated in 1941, but little of it was destined to increase crude-oil capacity, as it was mostly earmarked for the production of such special commodities as butadiene, aviation gasoline, and toluene. Only one new plant of 4,000 barrels crude oil capacity was being built on January 1, 1942, and additional crude oil capacity of 39,400 barrels was under construction at refineries already in existence.

Although the total number of refineries dropped from 562 to 523, their daily capacity rose from 4,860,194 barrels to 4,999,999, due largely to elimination of shut-down plants of small capacity, which declined in number from 136 to 92, and additional capacity completed for existing plants. The number operating increased from 420 to 430 and their daily capacity from 4,180,588 to 4,496,843 barrels. The largest increases in capacity were in the Texas Gulf Coast, California, and Indiana, Illinois, Kentucky, etc., districts, where the gains were 163,000, 157,000, and 149,000 barrels, respectively.

Cracking capacity rose from 1,151,193 barrels of gasoline output daily on January 1, 1941, to 1,222,684 on January 1, 1942. A decline in both the capacity shut-down and that under construction made the operating capacity 1,144,594 barrels compared with 1,021,006 on January 1, 1941.

Emphasis in refinery construction during 1941 centered on aviation gasoline refineries, but interest in synthetic rubber plants developed at the end of the year. The former include catalytic cracking plants,

polymerization plants, alkylation plants, isobutane and isopentane plants, and aviation-base stocks plants.

Production of high-octane blending agents by the alkylation method is rapidly supplanting the method of polymerizing butane to iso-octene followed by hydrogenation of the codimer obtained. The principal reason for this is that the alkylation method involves both a lower investment and lower operating costs. In addition to the thermal alkylation and the low-temperature sulfuric acid catalytic methods of alkylation described in a previous Minerals Yearbook, a patent was granted late in 1941 covering an alkylation method using hydrofluoric acid as a catalyst. One of the principal advantages claimed for this method is the ability to use propane as well as butane for a charging stock in addition to the advantage of being able to operate at normal temperatures, thus eliminating the need for refrigeration.

One plant to be completed early in 1942 will produce a new aviation-gasoline blending agent—cumene or isopropyl benzene.

Summary of refinery capacity in the United States, January 1, 1938–42

Year	Number of refineries				Capacity (barrels per day)			
	Operating	Shut down	Building	Total	Operating	Shut down	Building	Total
1938	431	120	10	561	[1] 3,970,196	[1] 380,955	[1] 283,020	4,634,171
1939	435	103	7	545	3,933,785	574,770	142,250	4,650,805
1940	461	86	10	557	4,196,694	431,952	92,567	4,721,213
1941	420	136	6	562	4,180,588	538,381	141,225	4,860,194
1942	430	92	1	523	4,496,843	459,756	43,400	4,999,999

[1] New basis; for complete information see Bureau of Mines Information Circular 7034.

The increase in production of 100-octane aviation fuel from 40,000 barrels to 120,000 barrels daily was one of the most important defense projects initiated in 1941. Efforts in this direction include concentration on production of crude oils yielding high-octane gasoline, increasing the production of butane, diversion of butane from other uses to serve as a source of iso-octane, isomerization of butane, and raising the tolerance of tetraethyl lead from 3 cc. to 4 cc. per gallon of gasoline.

The high boiling range of iso-octane, 225°–263° F. (see Minerals Yearbook, 1940, Review of 1939, p. 991), necessitates blending it with other agents to produce an aviation fuel of required volatility. These blending agents usually are a light-gravity cut of straight-run gasoline of high octane number or a catalytically cracked gasoline, with isopentane. The naphthenic-base crude oils, which traditionally have been considered less desirable because of their low gasoline content, make the highest-octane gasoline, although the cut suitable for use as an aviation-fuel blending agent usually is very small. Texas, California, and Louisiana are the sources for most crude oils of this type.

The need for increasing the production of butane is most essential, both for the production of 100-octane fuel and for the synthesis of rubber. Greater efficiency in its recovery and the use of more absorber oil should supply a quantity that heretofore has been wasted, estimated by one authority at 15,000 barrels daily compared with 40,000 barrels used. An additional amount probably will have to be produced from the cracking of oils.

The program also contemplates the diversion of butane used as liquefied petroleum gas, which is burned by about 2 million users on farms, in homes, and in industrial plants that have no convenient access to gas mains. Sales of this product, totaling 7,463,000 barrels in 1940 and estimated at about 11,500,000 barrels in 1941, comprised 1,835,000 barrels of butane, 2,600,000 barrels of propane, 2,937,000 barrels of butane-propane mixtures, and 91,000 barrels of pentane. Twenty-eight percent of the butane and 35 percent of the butane-propane mixtures served for domestic uses; 43 percent of the butane and 3 percent of the mixtures served for industrial uses; 14 percent of the butane and 34 percent of the mixtures were used in internal-combustion engines—principally trucks; 14 percent of the butane and 3 percent of the mixtures were used by gas companies; and 25 percent of the mixtures was used in chemical manufacture. These users probably will have to depend largely on propane, 63 percent of which was consumed by domestic users and 30 percent for industrial fuel in 1940.

Isomerization is the changing of one chemical compound to another with the same percentage composition and molecular weight but with different physical properties. Applied to butane, it is the process of changing that gas, which is inert in the alkylation process, to isobutane. The most usual raw materials for alkylation (which, as it pertains to the petroleum industry, brings about direct union of a paraffin molecule with an olefin molecule) are isobutane (C_4H_{10}) and butene (C_4H_8). When these products are alkylated they produce iso-octane (C_8H_{18}), a saturated isoparaffin. Small proportions of natural gas consist of butane and isobutane, both constituents having the same chemical formula but isobutane having what is termed a "branched-chain molecule." To be used in the alkylation process, the butane must be isomerized to isobutane by a catalytic process.

Considerable research has been made on isomerization in recent years, and several processes have been developed. Aside from their principal use of converting butane to isobutane, they can be applied (although not economically at present) to other hydrocarbons to produce the iso, or branched-chain molecules, which make a higher-octane fuel than normal molecules. Construction of a number of butane isomerization plants was started in 1941.

It is sometimes necessary to convert butane to butene by dehydrogenation where the still gases do not furnish sufficient olefins to make a balanced feed stock for the alkylation process. This is done by removing 2 hydrogen atoms from the butane molecule by catalytic reaction, changing it from C_4H_{10} to C_4H_8.

The deleterious effect of tetraethyl lead on motors long ago made it necessary to limit the proportion of this antiknock component in motor fuel. Although the Navy has permitted as much as 6 cc. a gallon to be used in its aviation fuel, specifications for all military gasoline in the recent past have set the limit at 3 cc. In December 1941 the maximum was raised to 4 cc. This will result in greater production of 100-octane gasoline by permitting lower-octane blending agents to be used.

Several hydroforming plants for aromatization of the nonaromatic constitutents of naphtha were either put in operation or were under construction during 1941. One such plant was designed to produce

a new solvent claimed to be superior in many ways to present solvents. Hydroforming, though, is of even more immediate importance in the production of toluene, essential in the manufacture of explosives. The proportion obtainable through aromatization of crude oil is very small, and the aromatic naphtha produced by the hydroforming process must go through several highly complicated operations for separation and purification of the toluene.

It is estimated that war needs will require about 1,500,000 barrels of toluene annually. Although production from coking operations amounted to approximately 700,000 barrels in 1941, most of this was required in the chemical industry and could be diverted only at a serious loss. The hydroforming plants now under construction probably will be able to supply the needs for this product, although not all of these plants have provided for production of toluene.

The synthetic rubber industry will compete with 100-octane gasoline for the supply of butane. Because almost all natural rubber comes from the East Indies, Japan's declaration of war precipitated a problem that theretofore had been considered only as a long-time project—that of manufacturing rubber. Of all the major countries at war, the United States is the best-situated to meet this problem. Although Germany and Russia have had more experience in producing synthetic rubber for practical use, they—particularly Germany—do not have the petroleum resources available to this country. The petroleum industry has been called upon to furnish rubber at the rate of 400,000 tons annually within 18 months. Butadiene, from which petroleum-synthesized rubber is polymerized (see Minerals Yearbook, Review of 1940, pp. 978–979), is made from butane and must share the supply of this gas with 100-octane gasoline.

MOTOR FUEL

Demand.—Total demand and domestic demand for motor fuel were both 12 percent higher than in 1940 (see fig. 8).

Domestic motor-fuel demand per motor vehicle in use increased from 19.7 barrels (827 gallons) in 1940 to 20.4 barrels (857 gallons) in 1941. Toll-bridge and other traffic statistics indicate that the truck traffic did not participate in the increased gasoline consumption to as great an extent as did passenger cars. Of 16 bridges in Kentucky, 13 showed a smaller proportion of truck traffic than in 1940, the average for all declining from 20.1 percent to 17.9 percent of the total passenger-car and truck traffic. Of 15 points throughout the rest of the country, 10 showed a smaller proportion of trucks, and the average for the 15 declined from 12.5 percent to 11.7 percent. This interruption in the increasing trend of truck traffic is reflected in the table entitled "Motor-fuel consumption per motor-vehicle unit in use on July 1, 1925–41."

Calculations from the gasoline-temperature index indicate that, because of favorable weather, gasoline consumption was 3,199,000 barrels more than might normally have been expected, particularly during the last 4 months of the year, as the spring, with the exception of April, was backward.

[2] In degrees departure from 46-year normal.

Production.—Motor-fuel production increased 12 percent—from 616,695,000 barrels in 1940 to 690,958,000 in 1941. The production in 1941 comprised 279,272,000 barrels of straight-run gasoline, 344,013,000 barrels of cracked gasoline, 3,469,000 barrels of benzol, and 64,204,000 barrels of natural gasoline. Natural gasoline used in producing motor fuel consisted of 47,825,000 barrels blended at the refineries and 17,808,000 barrels sold as such, including 1,429,000 barrels withdrawn from stocks in addition to the quantity produced.

Straight-run gasoline represented only 40.4 percent of the motor fuel produced, compared with 42.7 percent in 1940, whereas the proportion of cracked gasoline increased from 47.7 percent to 49.8. The ratio for natural gasoline blended at refineries was 6.9 percent, and that sold directly as such was 2.6 percent—a total of 9.5 percent compared with 9.0 percent in 1940. These figures include 0.2 percent contributed from stocks rather than production in 1941.

Production of gasoline in the United States in 1941, by methods of manufacture, districts, and months [1]

[1] Subject to revision.

[2] Based upon crude runs to stills.

Yields.—The yield of gasoline, which had dropped from 45.0 percent of the crude oil run to stills in 1939 to 43.1 percent in 1940, partly recovered in 1941 to 44.2 percent. The yield of straight-run gasoline, however, continued its downward trend, slipping from 20.4 percent in 1940 to 19.8 in 1941, whereas cracked gasoline, in response to increased re-forming, additional catalytic cracking, and other improved methods of motor-fuel production, rose from 22.8 percent in 1940 to 24.4 percent in 1941. The yields of straight-run gasoline stayed within a narrow range throughout the year, showing no trend, but those of cracked gasoline rose almost every month from a low of 23.3 percent in February to a high of 25.8 percent in December when the total yield was 45.7 percent.

Greatest gains in yields were in the Texas Gulf Coast, Louisiana Gulf Coast, California, and East Coast districts, which increased 2.7, 1.7, 1.6, and 1.4 percent, respectively. Yields in the Rocky Mountain, Appalachian, Indiana, Illinois, Kentucky, etc., and Inland Louisiana-Arkansas districts declined 1.1, 0.9, 0.8, and 0.6 percent, respectively.

Prices.—There were few advances in the refinery price of regular-grade gasoline after the request of the Office of Price Administration and Civilian Supply late in May to make no more increases without prior consultation with that office; in fact, the last one occurred early in July. During this period the Mid-Continent price for regular-grade gasoline rose from an average of 4.75 cents to 6.19 cents, at which quotation it held for the remainder of the year. Premium grade continued to advance until November 28, although a ceiling had been established in the Gulf Coast area on September 4. The Mid-Continent price for this grade rose from an average of 4.94 cents at the beginning of the year to 7.15 cents after the last increase.

Service-station prices for gasoline advanced steadily throughout the year until December 1, and thereafter suffered a late seasonal decline. Most of these gains occurred within the first 8 months of the year, as the Office of Price Administration and Civilian Supply established a ceiling for them on August 28 for 40 cities in the northern part of the East Coast district. There were only a few increases after that date, principally in the Southeast and Midwest.

The posted price does not indicate the real amount received for the gasoline, as under the dealer-marketing plan now in effect in most States a retailer determines his own price for the gasoline he sells. At the beginning of the year discounts from the posted price, ranging as high as 3 cents a gallon, were quite general in some places. However, by the end of the year they had been nearly eliminated, owing partly to the strong demand for gasoline during the third quarter (which taxed the sources of supply) and partly to the shortage of gasoline on the East coast caused by the loan of tankers to Great Britain, with the resultant difficulty of transporting oils from the Gulf Coast area to the East coast.

The greatest change occurred in the East Coast district, where the averages increased 2.49 cents for South Atlantic cities and 1.91 cents for North Atlantic cities. These gains were particularly significant because almost one-third of the motor-fuel demand is marketed in this district. The price in Salisbury, N. C., increased the greatest—4.45 cents (from 10.50 cents (ex tax) to 14.95), and Charlotte, N. C., followed closely, with an increase from 10.00 cents to 14.40. The price in Burlington, Vt., increased 3.9 cents (from 9.80 cents to 13.70);

that in Syracuse, N. Y., increased 3.6 cents and that in Atlanta, Ga., and Manchester, N. H., 3.5 cents each. Des Moines, Iowa, where the price dropped from 12.90 cents to 10.90, had the greatest decrease of the few cities where gasoline prices declined.

[2] 67-69 octane (L-3 method) discontinued April 11, 72-74 octane (A. S. T. M. method) initiated April 8.
[3] American Petroleum Institute, compiled by The Texas Co.

Despite the increases, the cities along the North Atlantic coast had the lowest average price for gasoline—12.59 cents (ex tax)—followed by the cities in the central part of the United States, where the prices averaged 12.87 cents.

The average price for the Rocky Mountain area rose from 13.75 cents (revised) on December 31, 1940, to 15.00 cents on December 31, 1941, to make it again the highest for the country, although the Pacific Coast area followed closely with an average of 14.80 cents.

The highest prices paid by motorists for gasoline, including State, City, and Federal taxes, on January 1, 1942, were 25.1 cents at Twin Falls, Idaho, and 24.1 cents at Boise, Idaho (each including 6.6 cents tax). The price in Montgomery, Ala., was 24.0 cents (including 9.5 cents tax); in Knoxville, Tenn., 23.50 (including 8.5 cents tax); in Charleston, W. Va., 23.05 cents (including 6.5 cents tax); and in Pensacola, Fla., 23.00 cents (including 9.5 cents tax). Motorists in Des Moines, Iowa, paying 15.4 cents a gallon, enjoyed the lowest price for their gasoline, although the service-station price in the principal Oklahoma cities was only 15.5 cents until a 1½-cent increase in the State gasoline tax on July 1 raised it to 17 cents.

Another advantage to refiners, in addition to the price advance, was the lower quality of motor fuel. One feature of gasoline quality had been its continual improvement for several years at no additional cost to consumers. (See Minerals Yearbook, Review of 1940, pp. 985–986.) During 1941, however, the military requirements for high-octane fuel resulted in a reversal of this trend to divert some of the high-octane qualities to military fuel. The rating for regular-grade gasoline, for

which the Western Refiners Association in 1940 had adopted the specification of 72–74 octane, was found in the Bureau of Mines Cooperative Fuel Research Motor-Gasoline Survey for the Summer of 1941 (see Report of Investigations 3611) to average almost 75 octane for the country as a whole. Late in 1941 the refiners in the Gulf Coast area reduced this grade to 71–72 octane and the premium grade from 80 to 78. Refiners in other parts of the country followed with similar reductions. Pressure brought on refiners to lower octane rating was due to a shortage in the raw materials for tetraethyl lead, which resulted in the Ethyl Gasoline Corporation rationing its supply of lead for civilian uses to meet military requirements.

Gasoline tax rates were increased in two States and the District of Columbia in 1941. Minnesota, which permitted its emergency tax of 1 cent a gallon to lapse on September 1, 1940, reestablished it, effective May 1, 1941, raising the tax from 3 cents to 4 cents. The tax in Oklahoma was increased from 5½ cents to 7 cents, effective July 1, and that in the District of Columbia from 2 cents to 3 cents, effective January 1, 1942. At the beginning of 1942 4 States had a tax rate of 7 cents, 1 of 6½ cents, 5 of 6 cents, 10 of 5 cents, 18 of 4 cents, 9 and the District of Columbia of 3 cents, and 1 of 2 cents.

Aviation gasoline.—Production of aviation gasoline in 1941 increased by about 50 percent, and more capacity was being added toward the end of the year as this country prepared to supply its allies with high-octane fuel for their war planes.

There were no changes in prices of aviation gasolines during 1941. Tank-wagon prices quoted by the Standard Oil Company of Ohio throughout the year were: Sohio Aviation, 14.5 cents; 74-octane, 15.5 cents; 87-octane, 16.5 cents; 100-octane, 24.5 cents.

Stocks.—Motor-fuel stocks were considerably lower throughout most of 1941 than they had been in 1940, and they maintained a more normal relationship throughout the year. The peak of 98,706,000 barrels of finished and unfinished gasoline on March 31 was 5 million barrels less than the peak on the same date in 1940 and represented only 52.2 days' supply compared with the 62.5 days' supply on March 31, 1940. Stocks again exceeded those of 1940 in October and totaled 94,098,000 barrels by December 31 compared with 84,409,000 barrels at the end of 1940. The days' supply on this date was 55.9 compared with 55.2 at the end of 1940.

All of the districts had larger stocks at the end of the year than at the beginning. The greatest gains occurred in the East Coast and Indiana, Illinois, Kentucky, etc., districts, the increase being 2,250,000 barrels (12.1 percent) in the former and 2,444,000 (15.4 percent) in the latter. Although stocks in the Texas Gulf Coast district gained 1,398,000 barrels—from 14,433,000 to 15,831,000—more than half of this was in unfinished gasoline, leaving the gain in finished gasoline only 663,000 barrels. This indicates how the refiners in the Gulf Coast area took advantage of the return in October of some of the tankers loaned to Great Britain to move gasoline to the East coast, where stocks increased 2 million barrels from the end of September to the end of December compared with a decline of almost that amount during the same period in 1940.

Stocks in the East Coast district dropped only a little below those of 1940 during the heavy consuming period, notwithstanding transportation difficulties. This was probably due to measures adopted by

[2] Includes stocks of finished gasoline at refineries, bulk terminals, and pipe lines.

The figures for days' supply on the chart represent the quantity of finished gasoline on hand at the end of the month divided by the total demand for the succeeding month.

Figure 9 also shows the stocks of distillate fuel oil for 1939–41, to stress the contrast in seasonal variations in stocks of the two products. It also shows the effect of the warm autumn of 1941 on the accumulation of a generous supply of heating oil, which was fortunate for the East Coast district, where distress might have been occasioned because of lack of transportation facilities for oil had the fall and winter been severe.

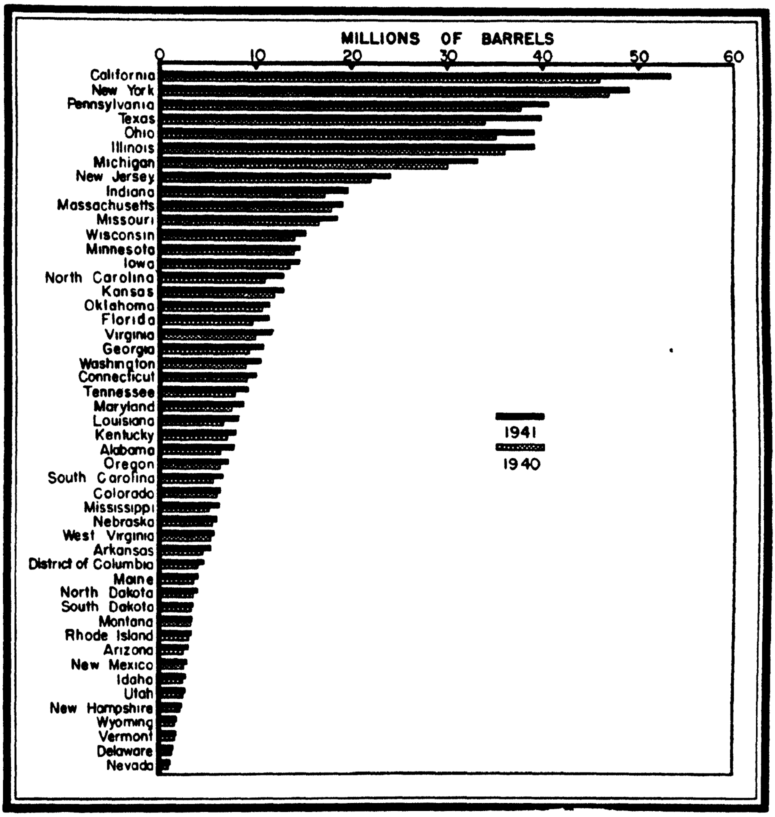

FIGURE 10.—Consumption of gasoline in the United States, 1940–41, by States.

Production and consumption by States.—Texas increased its relative standing by furnishing 32 percent of the gasoline produced in 1941. Percentages for the next important States were California, 13; Pennsylvania, 8; and Indiana and Illinois, 7 each.

The same six States that led in gasoline consumption in 1940 were highest in 1941, but California took first place and Texas stepped up to fourth (see fig. 10). The percentage consumption of the principal States was as follows: California, 8.3; New York, 7.7; Pennsylvania, 6.3; Texas, 6.2; Ohio, 6.1; Illinois, 6.1; Michigan 5.2.

Distribution.—The withdrawal of a large number of tankers from domestic service during the summer and fall of 1941 for loan to Great

Britain necessitated considerable change in gasoline-transportation channels. Fullest use was made of tank cars, and this movement amounted to about 150,000 barrels a day during the heavy motoring period. Although domestic shipments of gasoline on the Mississippi River and its tributaries had increased from 59,183,000 barrels in 1939 (unadjusted for duplications) to only 60,289,000 in 1940 (the latest data available), barge movement up the Mississippi River in 1941 almost doubled and amounted to 13,736,000 barrels compared

[8] Missouri and eastern Nebraska included with Kansas.
[9] Tennessee included with Kentucky.
[10] Rhode Island included with Massachusetts.
[11] Utah included with New Mexico.

with 7,941,000 in 1940. More significant, however, is the fact that the daily average, which was only 16,171 barrels for the first quarter of 1940, totaled 44,602 barrels for the peak months of June to September in 1941.

Notwithstanding the diversion of tankers, shipments of gasoline from the Gulf to the East coast increased from 119,142,000 barrels in 1940 to 130,534,000 in 1941, and even during the 5 months of the diversion period—June to October—they were 3,869,000 barrels more than for the same period in 1940. The tanker movement from California to the East coast, which gained 30 percent in the first 6 months of 1941 (from 1,737,000 barrels in 1940 to 2,251,000 in 1941) was completely stopped during the latter part of the year, so that the ships could be used for more necessary service. A small quantity of gasoline needed for special blending purposes continued to be moved across the country by railroad.

Shipments of motor fuel by pipe lines in the United States in 1941, by months

Pipe-line shipments of motor fuel increased from 96,657,000 barrels in 1940 to 111,077,000 in 1941. Important additions to pipe lines in 1941 include the Southeastern Pipe Line from Port St. Joe, Fla., to Chattanooga, Tenn.—450 miles; the Plantation Pipe Line from Baton Rouge, La., to Greensboro, N. C.—1,260 miles; and a line from Fall River to Worcester and Waltham, Mass.—86 miles. Work was begun in 1941 on a line from Marcus Hook, Pa., and Baltimore, Md., to Greensburg, Pa., via Schaefferstown, Pa.

KEROSINE AND RANGE OIL

The domestic demand for kerosine in 1941 changed little from the 1940 total of 68,776,000 barrels, and exports remained at a very low level in 1941, as in 1940. Kerosine is seldom imported into the United States; however, small quantities were received in both 1940 and 1941. Production of kerosine in 1941 was below the 1940 output, but year-end stocks for the 2 years remained at about the same volume.

Although 9 percent more crude petroleum was run to stills in 1941 than in 1940, the production of kerosine declined by 2 percent (from 73,882,000 barrels in 1940 to 72,586,000 in 1941) owing to a pronounced reduction in the percentage yield. The 5.2-percent yield of kerosine in 1941 (the lowest since 1936) compares with a relative high output of 5.7 percent in 1940. Refiners adjusted their runs to stills in 1941 to produce relatively more motor fuel and heavy fuel oil and correspondingly less kerosine and distillate fuel oil; however,

because of the larger quantity of crude petroleum processed in 1941, the change provided enough kerosine to satisfy all demands and to increase stocks slightly.

Substantial gains in the production of kerosine were reported for the Indiana-Illinois and Louisiana Gulf Coast refinery districts in 1941 compared with 1940. Small increases in kerosine production were also realized in the Oklahoma-Kansas, Texas Inland, Arkansas-Louisiana Inland, and Rocky Mountain refinery areas. The out-

put of kerosine declined sharply in the East Coast, Texas Gulf Coast, and California districts, owing to the lack of an active export market and the change in refinery runs to yield more motor fuel and heavy fuel oil.

Year-end stocks of kerosine increased by 1 percent from 9,512,000 barrels in 1940 to 9,599,000 in 1941, both totals representing 51 days' supply at the prevailing demand in the respective years. There were some shifts in the proportionate quantities of kerosine held in the several refinery districts at the end of 1941 compared with 1940. The inventory credited to the Indiana-Illinois area increased from 10 percent of all kerosine in storage at the close of 1940 to 12 percent in 1941, whereas quantities in the Texas Gulf Coast district declined from 33 percent of the 1940 total to 31 percent in 1941. California stocks of kerosine in 1941, representing 10 percent of the national total, were proportionately 2 percent below the quantity reported at the end of 1940. The East coast stocks remained at approximately 26 percent of the total inventory for both 1940 and 1941.

Distributors reported sales of 67,662,000 barrels of kerosine for range-burner fuel, tractor fuel, and all other uses in 1940, a 13-percent gain over 1939 deliveries of 59,767,000 barrels. Range burners, widely used in the New England States and in New York, New Jersey, Pennsylvania, and Illinois and to a lesser degree in other areas, required the larger share of the marketed kerosine as fuel. Kerosine sold as range oil increased from 33,841,000 barrels in 1939 (57 percent of total kerosine sales) to 40,715,000 in 1940 (60 percent of total demand). Remaining kerosine deliveries in 1940 were reported as tractor fuel—4,683,000 barrels (4,346,000 in 1939)—and all other uses—22,264,000 barrels (21,580,000 in 1939).

[1] Figures for 1941 by States not yet available.

Some light fuel oil (No. 1 grade) is sold for range fuel and should be added to the kerosine to determine the total demand for range fuel. Light fuel oil reported as range oil in 1940 totaled 3,977,000 barrels compared with 3,220,000 in 1939. Total range-oil sales (kerosine plus No. 1 fuel oil) were 44,692,000 barrels in 1940 or 21 percent over 1939 requirements of 37,061,000.

Sales of range oil in the United States, 1938–40, by States [1]

[1] Figures for 1941 by States not yet available.

There was an upward trend in kerosine prices in 1941. As an example, quotations for 41°–43° water-white kerosine at refineries in Oklahoma averaged 4.41 cents a gallon in 1941 compared with 4.04 cents in 1940. An average price of 4.12 cents per gallon in January, 1941, rose gradually during the spring months of the year and reached 4.56 cents in June and then remained at that level until the end of the year. The generally higher prices for kerosine in 1941 are reflected in the representative Chicago tank-wagon quotations, which increased from 10 cents a gallon in April to 10.5 cents in May. This top price did not hold, however, but settled to 10.3 cents in June, which quotation was in force until the end of 1941.

FUEL OIL

Increased refinery production, greater use of crude petroleum as fuel oil (transfers), a larger volume of imports, and curtailed exports were all factors that enabled oil companies to supply an increased domestic demand for fuel oil at fairly stable prices and to add slightly to stocks in 1941 compared with 1940. In other words, available supplies of fuel oil were ample in 1941 to satisfy an increased domestic demand and to maintain stocks without any appreciable advance in prices during a period when market quotations for most commodities were trending sharply upward.

In 1940 the domestic demand for fuel oil—501,014,000 barrels, a record up to that time—was exceeded by 11 percent in 1941, when heavy industries, such as railroads, gas and electric power plants, and manufacturing concerns, as well as the United States Navy, required substantially increased quantities of fuel oil. The weather in 1941 was comparatively mild in some important oil-heating areas compared with 1940, so that distillate fuel oils, mostly used for space heating, did not show a comparative increase in demand, as did that reported for residual grades or heavy fuel oils used for industrial purposes and for the Navy.

[3] Includes 213,673,000 barrels produced by cracking.

[4] Includes 56,870,000 barrels produced by cracking.

[5] Includes 224,639,000 barrels produced by cracking.

[6] Figures not available.

[7] Interstate Commerce Commission; total includes Diesel fuel.

[8] Federal Power Commission.

[9] U. S. Department of Commerce.

The Bureau's annual survey covering the distribution of fuel-oil sales by States and principal uses is still incomplete for 1941, so little is known about the various demands, except for releases covering certain requirements by other Government agencies, and for estimates. Monthly statistical statements compiled by the Interstate Commerce Commission show that Class 1 railroads purchased 83,563,000 barrels of fuel oil (including 2,838,000 barrels of Diesel fuel) in 1941—a 25-percent gain over 1940 requirements of 67,131,000 (including 1,933,000 barrels of Diesel fuel). The Department of Commerce, did not release monthly export statistics, including bunker-oil loadings on vessels engaged in foreign trade after September 1941. The 9-month total for 1941 is 23,000,000 barrels of bunker fuel compared with 27,008,000 in the same period of 1940—a 15-percent decline—and it is believed that the total for all of 1941 will show a similar loss. No monthly

records covering oil bunkers lifted by vessels engaged in coastwise trade are available, but it is unlikely that this demand will show any gain or enough gain to counterbalance the loss in foreign bunker loadings, so that the total bunker-oil requirements in 1941 as revealed by the annual fuel-oil sales survey probably will show a total below the 1940 item of 74,803,000 barrels. Monthly releases of the Federal Power Commission indicate 20,259,000 barrels of fuel oil purchased by public-utility electric-power companies in 1941—a gain of 21 percent

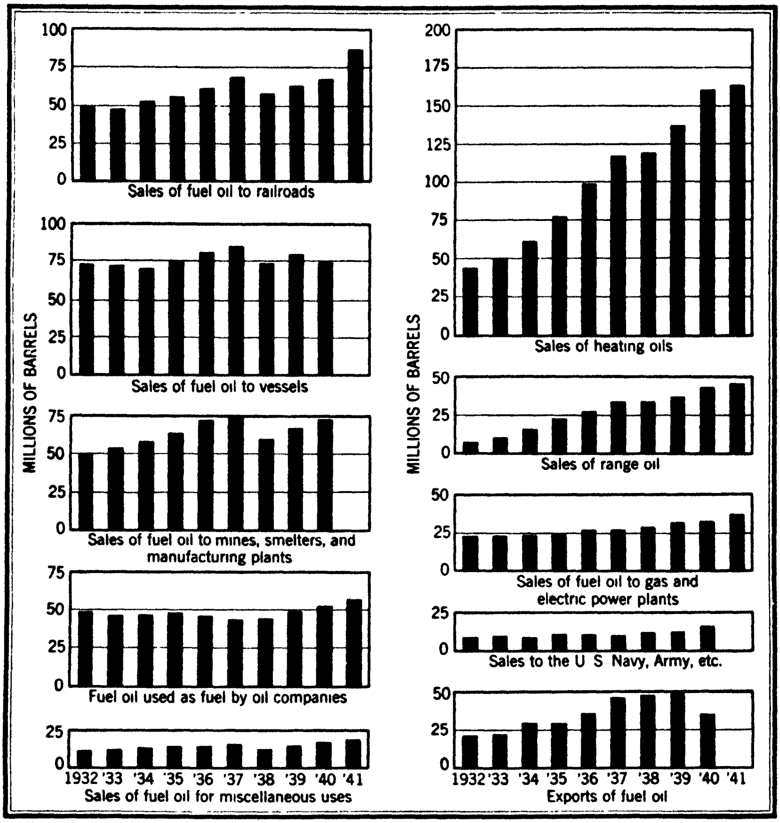

FIGURE 11.—Sales of fuel oil and range oil in the United States, 1932–41, by uses.

over the 1940 quantity, 16,772,000 barrels. When the fuel-oil purchases of the gas-manufacturing companies in 1941 compiled by the American Gas Association are added, it is believed that the fuel oil required by electric-power and gas-manufacturing industries will total approximately 39,000,000 barrels in 1941 compared with 32,795,000 in 1940. Estimates for other principal demands for fuel oil in 1941 are as follows: Smelters, mines, and manufacturing industries, 85,000,000 barrels; heating oils, 163,500,000; and oil-company fuel, 53,000,000.

Principal uses of fuel oil for the years 1932–41 are shown graphically in figure 11. The columns for 1932–40 are based upon totals derived from the Bureau's annual survey of fuel-oil sales, whereas those for 1941 are upon an estimated basis. Both distillate and residual fuel

oils are included. The range oil represented is all kerosine for the years 1932–36 and kerosine plus No. 1 fuel oil sold as range oil for subsequent years.

An export total for distillate and residual fuel oils for all of 1941 comparable with the 1940 quantity of 35,249,000 barrels is not available because of censorship regulations. However, exports of 22,196,000 barrels (including shipments to noncontiguous Territories of the United States) for the first 9 months of 1941 are 21 percent below the comparative total for 1940 of 28,043,000 barrels. The 11,400,000 barrels of distillate fuel oil reported as exported during the first three quarters of 1941 are 27 percent under the 15,579,000

[2] Figures for 1941 not yet available.

barrels shipped abroad in the same period of 1940. The foreign demand for American residual fuel oil also declined but to a lesser degree than for the lighter grades. Exports of heavy fuel oils decreased 13 percent from 12,464,000 barrels for the January–September interval of 1940 to 10,796,000 barrels in the same months of 1941. The fact that the export trade in distillate fuel oils, following the trend noted in 1940, declined to a greater degree than for the heavy grades is understandable, as under war conditions heavy fuel oil required for industrial and bunker fuel by foreign countries is given priority in shipping space over the lighter fuel oils, the use of which can be curtailed more easily.

Crude runs to stills increased by 9 percent in 1941; however, the production of fuel oil did not show a proportionate gain, as the yield for the fuel fractions declined from 38.6 percent in 1940 to 37.7 in 1941. Refiners reported the production of 531,544,000 barrels of fuel oil in 1941—a 6-percent increase over the quantity in 1940. Considering distillate and residual fuel oils separately, it is found that the lower percentage yield for fuel oil in 1941 was confined to the lighter grades (14.2 percent in 1940 and 13.4 in 1941); consequently the gain in production for this group—189,177,000 barrels in 1941 compared with 183,304,000 in 1940—was only 3 percent, although 9 percent more crude oil was run to stills. The principal factor that determined the lower yield for distillate fuel oil in 1941 was, it is believed, the less active market for domestic heating oils, owing to mild weather in some areas. Accelerated activities in 1941 by railroads, gas and electric-power plants, manufacturing establishments, the United States Navy, and the oil companies—all important users of heavy fuel oils—created a market demand that forced the oil refiners to maintain the yield of this fuel at the 1940 level (24.4-percent yield in 1940 and 24.3 in 1941); consequently, the 8-percent gain in production (342,367,000 barrels produced in 1941 compared with 316,221,000 in 1940) approximately paralleled the increase in crude runs to stills.

Refiners operating in districts east of California, lacking an incentive in 1941 to produce above-normal quantities of light heating oils, as was done in 1940, lowered the percentage yield for distillate fuel oils (14.2 percent in 1940 and 13.5 in 1941); as a result, the gain in production was only 4 percent in 1941 compared with an 18-percent increase in 1940. A review of the output of light fuel oils in the various refinery districts for 1941 compared with 1940 shows smaller percentage gains in 1941 in most areas of large volume production (East Coast, 31-percent gain in 1940 and 2 in 1941; Indiana, Illinois, Kentucky, etc., 26-percent gain in 1940 and 10 in 1941) and an actual decline in the Texas Gulf Coast area, the most important of all, from a 14-percent increase in 1940 to a 4-percent decline in production in 1941. The lower relative outputs in these districts in 1941 counterbalanced larger percentage gains reported for areas where the production of distillate fuel oil is less significant as a source of national supply. Comparative percentage increases in production of light fuel oil for two representative refinery districts in the latter grouping are as follows: Oklahoma, Kansas, and Missouri, 7-percent gain in 1940 and 16 in 1941; and Louisiana Gulf Coast, loss of 4 percent in 1940 contrasted with a 17-percent gain in 1941. The production of distillate fuel oil in California has declined in recent years from 30,023,000 barrels in 1939 to 28,418,000 in 1940 and to 27,803,000 in 1941, because

[1] Figures represent crude oil used as fuel on pipe lines. [2] Subject to revision. [3] Publication suspended. [4] Figures not available.

of a dwindling export trade and an approximately stationary domestic demand. However, increased runs to stills in 1941, even with a lower percentage yield (14.1 percent in 1940 and 13.0 in 1941), supplied light fuel oils adequate to satisfy all demands and to increase year-end stocks from 10,065,000 barrels in 1940 to 12,713,000 in 1941.

Oil companies operating refineries east of California produced 253,956,000 barrels of residual fuel oil in 1941, a gain of 9 percent over the 1940 quantity. The increase in residual output in 1941 was in direct proportion to the gain in crude runs in the area, and the percentage yield was not a factor, as it remained approximately 21 percent for both 1940 and 1941. All refinery districts east of California reported gains in residual-fuel-oil output except the East Coast, which declined for the second consecutive year. The fact that the production of heavy fuel oil on the Atlantic coast dropped by 6 percent from 53,252,000 barrels in 1940 to 50,113,000 in 1941 would not be expected under conditions prevailing in 1941, as the market demand was brisk and crude runs to stills increased by 6 percent; furthermore, the proportion of foreign crude (which has a high residual-fuel-oil content) processed was greater (22 percent of total runs in 1941 compared with 16 in 1940). However, as the percentage yield of heavy fuel oil for the East Coast district declined from 26.0 percent in 1940 to 23.1 in 1941, it is evident that refiners did not cater to the heavy-fuel-oil market beyond supplying contract customers but adjusted their runs to make more profitable products such as gasoline, the percentage yield of which increased. The expanding market for heavy fuel oil in 1941 is reflected in the increased production in all other refinery districts east of California. The Indiana, Illinois, Kentucky, etc., area reported 24 percent more residual-fuel-oil production in 1941 than in 1940, and districts supplying heavy fuel oil for tanker shipments to the East coast, namely, Texas Gulf, and Louisiana Gulf, stepped up their output 8 and 32 percent, respectively, in 1941 over 1940. California refiners, attempting to meet naval and industrial demands for residual fuel oil, increased production by 6 percent to 88,411,000 barrels in 1941 compared with a 3-percent gain in 1940 over 1939.

The fuel-oil supply in some areas is supplemented by burning non-gasoline-bearing crude petroleum directly as fuel.. Crudes thus used are termed "transfers" in the petroleum statistics of the Bureau of Mines and must be added to other supply items, such as production, imports, and draft on stocks in computing the indicated domestic demand for fuel oil. Light crudes used as fuel by pipe lines are credited to distillate fuel oils, and heavy crudes burned on leases and as industrial fuel are added to residual fuel oils. Transfers reported for 1941 totaled 15,482,000 barrels—a 51-percent gain over the corresponding item for 1940. All of the increase in transfers is found under residual fuel oil, and the quantity was up by 68 percent from 7,699,000 barrels in 1940 to 12,969,000 in 1941. Transfers added to the distillate-fuel-oil supply in 1941, 2,513,000 barrels, were slightly below the 1940 quantity—2,576,000 barrels. There was some gain in transfers to residual fuel oil in areas east of California (3,629,000 barrels in 1940 and 4,095,000 in 1941—a 13-percent increase), but most of it was reported from California, where, because of the pressure for naval and industrial fuel, the 1941 transfers of 8,874,000 barrels more than doubled the 1940 total of 4,070,000. The larger share of transfers classified as distillate fuel oil is confined to districts east of

[3] Publication suspended.
[4] Figures not available.

California, where the total increased by 4 percent to 2,383,000 barrels in 1941. Only minor quantities of transfers of light crude to the distillate-fuel-oil account are found in the statistics for California, and the total has diminished from 616,000 barrels in 1939 to 279,000 barrels in 1940 and 130,000 in 1941.

No release of petroleum import statistics was made after September 1941, owing to censorship regulations. A total of 27,289,000 barrels of fuel oil was imported in the 9-month period of 1941—a 22-percent increase over the 22,304,000 barrels received in the same months of 1940. The distillate fuel oil brought into the country from January through September 1941—3,707,000 barrels—was 57 percent above receipts in the corresponding months of 1940, and residual fuel oil received from abroad in the same period of 1941 was 23,582,000 barrels—an 18-percent increase over the comparative 1940 total of 19,940,000.

Total fuel-oil stocks changed very little during 1941. Stocks of 133,121,000 barrels on December 31, 1941, were less than 1 percent above the 132,244,000 barrels in storage at the close of 1940. However, if distillate- and residual fuel-oil stocks are reviewed separately, it is noticed that the light-fuel-oil inventory of 49,926,000 barrels is 16 percent above the 42,940,000 held at the end of 1940, whereas the heavy fuel oil in storage declined by 7 percent from 89,304,000 barrels in 1940 to 83,195,000 in 1941. The export market for distillate fuel oil declined sharply in 1941; furthermore, the gain in domestic demand was not outstanding as in 1940, consequently there was a surplus to send to storage. Oil companies, however, even with greater supplies of residual fuel oil from increased production, imports, and transfers from crude, were forced to draw on stocks in 1941 to satisfy a very active domestic market and a fair export demand.

Distillate-fuel-oil stocks held east of California increased by 13 percent or from 32,875,000 barrels in 1940 to 37,213,000 in 1941. All refinery districts in this territory reported stock increases for distillate fuel oils in 1941 except the Texas Gulf—an important supply area for the East coast—and the Rocky Mountain area, where the volume of stocks is comparatively small. A large share of the light fuel oil used in the important East coast market is normally brought in by tankers from Gulf coast refineries; consequently, it is desirable to maintain large quantities in storage, especially during the heating season. Stocks in the East coast area increased by 17 percent—from 15,922,000 barrels in 1940 to 18,631,000 in 1941—even though numerous tankers were diverted for war purposes. Large percentage gains in distillate-fuel-oil stocks in 1941, reported for refinery districts where volumes held are comparatively important, were as follows: Indiana, Illinois, Kentucky, etc., 29 percent; Oklahoma, Kansas, and Missouri, 44 percent; and Louisiana Gulf Coast, 13 percent. Oil companies operating in the California district, faced with a static domestic demand and a declining export trade in distillate fuel oils in 1941, sent large enough quantities to storage to increase the 1941 total to 12,713,000 barrels—a 26-percent increase over the 1940 year-end inventory of 10,065,000.

The 7-percent decline in total residual-fuel-oil stocks held at the end of 1941 compared with 1940 was largely associated with an 11-percent decline in important quantities stored in California, as inventories for

the refinery districts east of California netted a 2-percent increase from 29,412,000 barrels in 1940 to 29,996,000 at the close of 1941. Six districts out of nine in the territory east of California showed residual-fuel-oil stock declines in 1941, so that the small net increase for the area as a whole is traceable to a 40-percent gain in the Indiana, Illinois, Kentucky, etc., district (2,972,000 barrels in 1940 and 4,152,000 in 1941), where production of residual fuel oil increased 24 percent in 1941, and to a 3-percent stock expansion in the Texas Gulf (8,486,000 barrels in 1940 and 8,710,000 in 1941). Heavy-fuel-oil stocks held in the Appalachian refinery district also rose by 54 percent in 1941, but the quantities involved are small. There was a fair increase (6 percent) in residual-fuel-oil production in California during 1941 plus greatly augmented (118-percent gain) transfers of non-gasoline-bearing crude to the heavy-fuel-oil account. However, the larger supply did not meet increased demands; consequently a heavy draft on stocks reduced the inventory from 59,892,000 barrels in 1940 to 53,199,000 at the end of 1941.

Beginning in July 1941, tanker movements from Gulf ports to the East coast were counted only when the cargoes were intended primarily for domestic consumption; that is, fuel oil in this coastal movement earmarked for Lend-Lease or defense purposes was excluded. The tanker shipment of fuel oils from Gulf refinery districts to the Atlantic seaboard, even with the limitation as to ultimate domestic use invoked in the second half of 1941, increased by 6 percent from 111,775,000 barrels in 1940 to 118,543,000 in 1941. The gain in this trade, however, was limited to residual fuel oils, the total of which increased by 13 percent from 67,346,000 barrels in 1940 to 75,923,000 in 1941. The lack of a strong market for distillate fuel oils on the Atlantic coast in 1941, coupled with the difficulty of securing tankers, is shown in the movement of light fuel oils from the Gulf to the East coast, which declined from 44,429,000 barrels in 1940 to 42,620,000 in 1941.

A strong market for residual fuel oils in California in 1941 and the difficulty in obtaining boats were factors in the sharp decline reported in the tanker movement of fuel oils from California to Gulf and East coast points. Light fuel oils in this movement dropped from 721,000 barrels in 1940 to 203,000 in 1941, and for heavy grades the quantity declined from 566,000 barrels in 1940 to a negligible item of 23,000 barrels in 1941.

Small quantities of fuel oil moved out of the California marketing area (California, Oregon, Washington, Arizona, and Nevada) by railroad tank cars and trucks to adjoining States. Shipments of distillate fuel oil in this overland movement increased from 282,000 barrels in 1940 to 382,000 in 1941, but heavy fuel oils declined from 198,000 barrels in 1940 to 130,000 in 1941.

Tanker rates for both "clean" boats (carrying light petroleum products) and "dirty" boats (carrying crude and heavy fuel oils) on the Gulf to North Atlantic route not east of New York averaged higher in 1941 than in 1940. The average rate paid to tankers for moving No. 2 heating oil on this run advanced from 52.6 cents a barrel in 1940 to 55.7 in 1941 and was double the 1939 average of 27.8 cents. The 1941 average of 56.9 cents a barrel for transporting heavy residual fuel oil over the same route was 10 cents above the 1940 average of 46.9 and more than twice the 1939 average of 25.8

cents. Incidentally the 1941 average rate for heavy fuel oil from the Gulf coast to North Atlantic points was slightly above the average quotation for No. 2 fuel oil in "clean" boats, which is unusual, as "dirty" boats in which crude oil and residual fuel oil are carried normally receive a lower rate per barrel.

The demand for "clean" tankers and their scarcity, owing to their diversion to other routes at the request of the Government, forced the Gulf coast-North Atlantic freight rate on light fuel oil up to 80 cents a barrel in December 1940. This high charge did not hold, however, and the quotation declined to 62 cents a barrel on January 6, 1941, and to 60 cents on January 20. The tanker rate, with the return of some boats to oil-company control and the larger share of the heating-oil load satisfied, declined to 42 cents on February 10 and to 40 cents on February 17, the lowest rate for the year; this quotation was double the low of 20 cents for 1940, in August of that year. A further shortage of tankers and the general uncertainty in shipping conditions started a rise in quotations in March 1941 to a month-end rate of 62 cents a barrel. The freight cost then declined to 57 cents a barrel on April 14 and remained at that level through November, after which month no rates were quoted.

The 1940 year-end rate of 66 cents a barrel for "dirty" boats used in transporting heavy residual fuel oil from the Gulf coast to North Atlantic points remained in force until February 17, 1941, when it dropped to 50 cents and then to 45 cents on February 24, the lowest quotation of the year and a rate well above the 20-cent-a-barrel low of 1940, in August-September of that year. The continued demand for tankers forced the freight quotation for residual fuel oil to 50 cents a barrel on March 17, to 55 cents on March 24, and finally to 57 cents on April 7, 1941, where it remained through November. No tanker rates were posted in December 1941.

The average price of representative fuel oils in 1941 differed only slightly from 1940 quotations. Increased production, a greater use of crude petroleum as fuel oil, a larger volume of imports, and a lower export demand were all factors which enabled oil companies to supply an active domestic market without applying the brake of higher prices. Two quotations of the several representative fuel-oil prices under review showed slight advances in 1941—the price of No. 2 straw fuel oil (widely used for domestic heating) at refineries in Oklahoma increased from an average of 3.47 cents a gallon in 1940 to 3.69 in 1941, and Diesel fuel for ships' bunkers at New York harbor was quoted at an average of $1.99 a barrel in 1941 compared with $1.98 in 1940. The average prices for other representative fuel oils remained unchanged or actually declined in 1941. Bunker C fuel oil for ships loading in New York averaged $1.34 a barrel for both 1940 and 1941, even though an average increase of 10 cents a barrel in the Gulf coast-North Atlantic tanker rate had to be absorbed in 1941. The price of Diesel fuel for ships' bunkers at Los Angeles also remained at an average of $1.40 a barrel for 1940 and 1941. The average quotation for several fuel oils declined in 1941 compared with 1940 as follows: Bunker C at Gulf ports 90 cents a barrel in 1940 and 87 cents in 1941; Bunker C at Los Angeles, 82 cents a barrel in 1940 and 80 cents in 1941; and Diesel fuel for ships' bunkers at Gulf ports, $1.64 a barrel average in 1940 and $1.56 in 1941.

Retail prices for various fuels are compiled by the Bureau of Labor Statistics, United States Department of Labor. Monthly releases of that Bureau show that No. 2 heating oil at Chicago averaged 7.73 cents a gallon for the first 3 months of 1941 or the same price as in the first quarter and in December 1940. The quotation declined to 7.47 cents a gallon in April 1941, and this price held until August, when a low for the year of 7.40 cents was reported compared with a low of 7.30 cents in the second and third quarters of 1940. The fall

[1] Platt's Oil Price Handbook.

heating demand forced up the price to 7.61 cents a gallon in September 1941 and to 7.65 cents in the final quarter—a quotation slightly above the average of 7.54 cents for the fourth quarter of 1940. The retail price of No. 2 heating oil in New York was 6.94 cents a gallon in January 1941, or the same as in the final month of 1940. The consumer price dropped to 6.45 cents a gallon in February 1941 and to 6.28 cents in March for the low of the year, a quotation just above the low of 1940—6.12 cents—reported for September and October of that year. Summer stocking by consumers forced up the price to 6.43 cents a gallon in April 1941 and then by gradual increases to 7.30 cents in October—the highest quotation of the year compared

with a top price in 1940 of 7.14 cents in March. There was a slight decline in the New York retail price of No. 2 fuel oil to 7.27 cents a gallon in November 1941.

LUBRICATING OIL

Domestic demand for lubricating oil increased more than 20 percent in 1941 over the 1940 record. Production increased 2,774,000 barrels to 39,539,000 barrels, exports declined, and 640,000 barrels were withdrawn from stocks. The greatest gain in demand for lubricating oil was in that used for industrial purposes, which increased 34 percent, although there was also a substantial gain in automotive consumption.

Foremost in the increased use of industrial types is cutting oil. Transformer oil has also had a large gain in demand; and the use of hydraulic oil, though not so important in the total, has expanded rapidly. A number of installations formerly operated by cable are now being controlled hydraulically. Many operations, for example, on large planes now under construction will have this type of control. The expanding demand for lubricants for aviation and for tanks, included under industrial uses, as well as for heavy-duty trucks, has caused requirements to change from a large proportion of neutrals to a larger proportion of bright stock. Whereas refiners were only recently considering means of cracking the bright stock to get a larger proportion of neutrals, they are now having difficulty supplying the demand for it.

Comparative analyses of statistics for lubricating oil in the United States, 1940–41, by months and districts

[1] Revised. [2] Subject to revision. [3] Publication suspended.

A decreasing ratio of lubricating oil used by motor vehicles in proportion to gasoline has retarded the growth in consumption of lubricants for several years. Prominent among the reasons for this are the practice among motorists of changing oil less frequently and the reclamation of used lubricating oil.

The reclaiming of lubricating oil has grown considerably in the last decade. Many fleet owners operate oil purifiers that neutralize acids and extract water and gasoline by heating the oil with a clay and then filtering it. Used oils and crankcase drainings are also collected from industrial plants, service stations, and garages, particularly in the northeastern part of the United States. Formerly a charge was made for collecting the oil, and it was used as fuel. Later, with the advent of renovation of used oil, collection was made gratis, and in recent years a cent or two a gallon has been paid for the oil. Renovating plants range from small ones that can perform only the simpler reclaiming operations of neutralizing the acids and extracting gasoline, water, and carbonaceous and other foreign solids to large refineries operating stills, treatment agitators, settling tanks, and complete modern filter plants. In the small plants the waste lubricants that are contaminated with heavy oils and greases can be prepared only for use as fuel.

Although the collection and reclamation of crankcase drainings are quite complete in densely populated parts of the country, there are many large towns and cities where their disposal is less economic—some instances even where this waste oil is run into the sewer or dumped in pits or on vacant lots. Other applications include the lubrication of molds for cement, clay products, etc.; rustproofing and

lubricating farming and mining equipment; and use as an insecticide for farm stock and buildings, as fuel, for laying dust on roads, driveways, and parking areas, for mosquito control, and in crankcases of older automobiles. An effort should be made during the war, particularly during transportation difficulties, to make the most economical use of crankcase drainings possible.

Lubricating-oil production totaled 39,539,000 barrels in 1941 compared with 36,765,000 barrels in 1940. The Texas Gulf Coast district maintained the lead, producing 9,677,000 barrels or 24.5 percent of the total. The East Coast district followed with 8,608,000 barrels or 21.8 percent, and the Appalachian was third with 6,414,000 barrels or 16.2 percent.

The decline of 640,000 barrels in stocks of lubricating oil—from 8,767,000 barrels on December 31, 1940, to 8,127,000 on December 31, 1941—left them higher than in any previous year since 1932 except 1940. The principal declines were in the Texas Gulf Coast, East Coast, and the Appalachian districts, where they dropped 389,000, 305,000, and 204,000 barrels, respectively. California had the largest gain—from 1,264,000 barrels to 1,359,000.

Average monthly refinery prices of 5 selected grades of lubricating oil in the United States, 1940–41, in cents per gallon [1]

[1] National Petroleum News.

A request of the Office of Price Administration and Civilian Supply on August 4, fixing the maximum price of Pennsylvania Grade neutral oil at 33 cents, retarded the rise in lubricating-oil prices. This grade had been quoted as high as 40 cents a gallon, and the average for July was 35.52 cents, or 14 cents higher than the price at the beginning of the year. The price of Pennsylvania steam-refined cylinder stock, after reaching an average of 16 cents during October, receded to 15.5 cents for the rest of the year, which was double the price prevailing at the close of 1940. Prices for Oklahoma neutral and

bright stock did not reach their high levels until November, when the Price Administrator established ceilings for refined products. The former stabilized at 15.25 cents and the latter at 22.75 cents, representing increases of 5½ and 9 cents, respectively, during the year.

OTHER PRODUCTS

WAX

The total demand for paraffin wax rose from 546,718,000 pounds in 1940 to 743,480,000 in 1941, and the domestic demand increased almost 50 percent. Stocks dropped from 125,272,000 pounds to 74,814,000, the lowest since 1933.

Production increased from 513,240,000 pounds in 1940 to 676,480,000 in 1941. The Louisiana Gulf Coast district made the greatest gain, as the production of 89,320,000 pounds more than tripled the 28,000,000 pounds produced in 1940; the increase in Texas Gulf Coast district—from 76,440,000 pounds to 122,640,000—came next. The Indiana, Illinois, Kentucky, etc., district was the only one where production declined. The East Coast district maintained first place, producing 233,520,000 pounds.

Prices for 122°–124° white crude scale wax, after receding slightly early in the year to a low of 2.5 cents a pound, began advancing until they reached a peak of 6.25 cents in September. The Price Administrator, however, set a maximum price of 4.25 cents effective December 1, which prevailed during the last month of the year.

COKE

The total demand for petroleum coke was 1,907,800 tons in 1941 compared with 1,705,600 in 1940. Stocks dropped to a record year-end low of 228,000 tons compared with 1,511,600 at the end of 1931. The Indiana, Illinois, Kentucky, etc., district furnished more than half of the 1,648,800 tons produced.

ASPHALT AND ROAD OIL

The total demand for asphalt in 1941—about 6,700,000 tons—represented a 24-percent gain over the 1940 demand of 5,420,400 tons. Production increased 1,210,900 tons to 6,557,600, but stocks decreased 10,000 tons to 604,000.

Road-oil production increased 1,378,000 barrels to 9,149,000, whereas domestic demand increased 1,131,000 barrels to 8,980,000. Stocks, which gained the 169,000 barrels difference, amounted to 793,000 barrels on December 31.

Detailed statistics on asphalt and road oil appear in the chapter on Asphalt and Related Bitumens.

STILL GAS

Production of still gas in 1941 amounted to 293,565 million cubic feet (equivalent 77,254,000 barrels) compared with 273,420 million cubic feet produced in 1940. Of the latter, 252,914 million cubic feet (92.5 percent) were used as refinery fuel, which, in terms of British thermal units, constituted more than half of all the heat utilized at refineries.

The Texas Gulf Coast district continued to lead in the production of still gas in 1941, with the Indiana, Illinois, Kentucky, etc., and East Coast districts following in order.

MISCELLANEOUS PRODUCTS

The output of miscellaneous oils in 1941 amounted to 3,986,000 barrels compared with 3,202,000 in 1940. The total demand increased from 3,119,000 barrels in 1940 to 3,961,000 in 1941.

Detailed data, by products, for 1940, the latest year available, indicate that almost all of the gain of 843,000 barrels in production for that year is attributable to a gain in production of liquefied petroleum gas, which increased 761,000 barrels. The refinery production of liquefied petroleum gas (1,719,000 barrels) constituted 23 percent of the sales and exports of that product in 1940 and is almost as large as the total sales in 1935.

WORLD PRODUCTION [2]

Although war was being waged over extensive areas of the earth, the world production of crude petroleum increased 4 percent from 1940 to 1941, if numerous unofficial statistics and estimates can be considered reliable. The increase was due largely to the 4-percent augmented yield in the United States, which comprised 63 percent of the world total both in 1940 and in 1941. Venezuela and U. S. S. R. also contributed considerably to the increased world output. Canada, Trinidad, Argentina, Hungary, and Egypt produced more oil in 1941 than in 1940. However, these increases in crude-petroleum production were in part offset by declines in the petroleum output of European and Asiatic countries, as well as in Mexico, Ecuador, and Peru.

The Western Hemisphere supplied 78 percent of the world output in 1940 and 79 percent in 1941. Production of crude in Venezuela, third in rank in the world, revived in 1941 from the decline of the preceding year and surpassed all previous records. The 23-percent increase from 1940 to 1941 was due primarily to greater output in the Maracaibo fields of Tia Juana, Lagunillas, Cabimas, El Cubo, and La Concepcion and secondarily to increases in Cumarebo, and in the Eastern fields of Oficina, Jusepin, San Joaquin, El Roble, and Santa Ana. Production at Mene Grande revived, whereas Quiriquire, Temblador, Bachaquero, and Pedernales showed declines. A promising new field, Santa Barbara, in northern Monagas, was brought in near the end of 1941.

Increased output in the Comodoro Rivadavia field, the major producer, and especially in Mendoza raised the petroleum production of

[2] By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

Argentina from 1940 to 1941, in spite of a decline in the Plaza Huincul field. The Government enterprise (Y. P. F.) increased its yield 12 percent and supplied 64 percent of the national production, but both the absolute output and the proportional share of the private companies declined.

In Colombia, both the De Mares and the Barco concessions showed smaller yield in 1941 than in 1940. In Peru, a sharp decrease in the Lobitos field offset an increase in the La Brea and Parinas fields and

Crude petroleum produced in principal countries of the world, 1937–41, in thousands of barrels

[1] Approximate production. Data derived in part from World Petroleum, vol. 12, No. 2, February 1941, pp. 20–21, and vol. 13, No. 3, March 1942, p. 88.
[2] Includes U. S. S. R. fields in Asia, other than Sakhalin.
[3] Approximate production.
[4] Exclusive of U. S. S. R. fields in Asia, other than Sakhalin, which are included with U. S. S. R. in Europe.

lowered the national output of petroleum. Ecuadorian production of crude petroleum also declined from 1940 to 1941.

In Mexico, although output of petroleum increased in the Naranjos and Isthmus fields, a decline in Poza Rica, the major producer, and in the Panuco field reduced the national output.

In Canada, the increased output of the limestone oil wells of Turner Valley, Alberta, raised the petroleum production of the Dominion.

In Europe, excluding U. S. S. R., Hungary was the only country that increased its petroleum production. Production in Rumania, the major producer of central and western Europe, was 10 percent less in 1941 than in 1940, if unofficial figures are reliable.

In Asia difficulties of transport arising from the war reduced petroleum production. The output in Iraq in 1941 was little more than half of the 1940 figure. Iran and the Netherlands East Indies curtailed their petroleum production in 1941. Production in Burma and British India remained virtually stationary. In contrast, Saudi Arabia showed a small increase.

In Egypt the prolific Ras Gharib field increased the national production of petroleum.

FOREIGN TRADE [3]

Imports.—Imports of mineral oils, crude and refined, into continental United States increased 7,360,000 barrels in the first 9 months of 1941 over the corresponding months of 1940. During the same period the domestic demand for all oils rose 116,459,000 barrels, whereas exports declined 27,198,000 barrels, giving an increase of 89,261,000 barrels in total demand from January–September 1940 to January–September 1941. As the production of crude petroleum, natural gasoline, and benzol was only 11,421,000 barrels higher in the first three quarters of 1941 than in the corresponding quarters of 1940, altogether 18,431,000 barrels were withdrawn from storage between January and September 1941 compared with additions of 52,049,000 barrels added to stocks during the first 9 months of 1940. Imports of mineral oils, crude and refined, constituted 5.9 percent of the total new supply in continental United States during the first 9 months of 1941 compared with 5.3 percent during the corresponding months of 1940.

The chief increases in imports of mineral oils into continental United States from January–September 1940 to January–September 1941 were in crude petroleum, residual fuel oil, and distillate fuel oil. These increases were offset to a considerable extent by a sharp drop in imports of unfinished oils for further processing.

Exports.—Continental United States continued to be a net exporter of mineral oils, but the excess of exports over imports in the first 9 months of 1940 was reduced from 42,764,000 barrels to 8,206,000 barrels in the corresponding months of 1941. The excess of exports over imports in the first 9 months of 1941 was in refined oils. Actually continental United States imported 10,715,000 barrels more crude petroleum than it exported during the first 9 months of 1941 compared with net exports of 10,194,000 barrels in the first three quarters of 1940. Owing to the war situation and the difficulty of shipping oils to Europe, net exports of gasoline, distillate fuel oil, lubricating oils,

[1] Imports of crude as reported to Bureau of Mines; imports of refined products compiled from data of Department of Commerce; figures may differ slightly from those used throughout other sections of this report.

and kerosine were less in the first 9 months of 1941 than in the corresponding months of 1940. Residual fuel oil constituted an exception to the refined oils, which are normally exported in greater quantities than they are imported. Net imports of residual fuel oil increased from 7,476,000 barrels in the first 9 months of 1940 to 12,786,000 barrels in the corresponding months of 1941.

In absolute amounts, exports and Territorial shipments of mineral oils, both crude and refined, were smaller from January to September 1941 than from January to September 1940. The sharpest decrease both absolutely and proportionally was in outward shipments of crude petroleum. Of the refined oils, the greatest decreases were in exports and shipments of motor fuel, of distillate fuel oil, of lubricating oils, and of residual fuel oil.

Mineral oils, crude and refined, shipped from continental United States and including shipments to noncontiguous Territories, January–September 1940–41, by classes and months [1]

[1] Compiled from the records of the Department of Commerce; figures may differ slightly from those used throughout other sections of this report.

[2] Includes benzol, natural gasoline, and (since June 1, 1940) antiknock compounds.

[3] Includes antiknock compounds beginning with June 1940. Data for January to May 1940, inclusive, may be found in motor-fuel section.

INTERCOASTAL SHIPMENTS [4]

Receipts of mineral oils, crude and refined, on the East coast from Gulf coast ports were slightly larger in 1941 than in 1940. Crude petroleum was the largest single item in these shipments and constituted 34 percent of the total shipments in 1941. However, shipments of crude petroleum from Gulf coast to East coast ports were 9.1 percent smaller in 1941 than in 1940. Increased shipments of refined oils, however, more than offset the decrease in shipments of crude petroleum from 1940 to 1941. The principal gain was in shipments of gasoline, which were 9.6 percent larger in 1941 than in 1940; however, less kerosine and less distillate fuel oil were shipped from Gulf coast to Atlantic coast ports in 1941 than in 1940.

NATURAL GAS [1]

By F. S. Lott and G. R. Hopkins [2]

SUMMARY OUTLINE

SUMMARY

The watchword of the natural-gas industry during 1941 was war service, as problems generated by the greatest industrial effort in history dominated policy and managerial activities in all parts of the country. These problems were mainly of four broad types: (1) Gas supply for expanding markets, particularly in the Appalachian region; (2) transportation facilities to bring gas to consuming centers whose requirements were growing rapidly; (3) availability of materials and equipment essential to effective functioning of gas utilities; and (4) measures to protect installations from possible damage by sabotage or enemy attack. As months passed, the solution of these problems became more urgent until hostilities opened on December 7, 1941. From that date it was fully realized that natural gas, wherever available, must aid war production without hindrance, despite increasing difficulties.

Marketed production of natural gas, in reaching a new high of 2,770 billion cubic feet in 1941, exceeded the record of 1940 by 4 percent (see fig. 1). The gain in demand was mostly from industrial consumers, as warm weather restricted domestic gas use to about the level of 1940. The sharpest gains were made in use by miscellaneous industrials (18 percent) and portland-cement plants (29 percent), which felt the full impetus of war demands.

The average value of natural gas at the producing wells is estimated to have reversed in 1941 the persistent decline of many years, and to have increased to 4.7 cents per thousand cubic feet from 4.5 cents in 1940. The chief causes were firming tendencies in the field price of gas in important southwestern fields and marked expansion of Appalachian gas production.

The average value at points of consumption increased to about 22.0 cents per thousand cubic feet in 1941 from 21.7 cents in 1940. A rise in the average industrial value to about 10.3 cents from 9.5 in 1940 is

[1] Data for 1941 are preliminary; detailed statistics with final revisions will be released later.
[2] Tables compiled by H. Backus, Petroleum Economics Division, Bureau of Mines.

thought to have more than balanced the effects of declines in domestic and commercial values. The total sales value of natural gas to ultimate consumers was about $608,000,000 in 1941—5 percent more than in 1940 and the highest on record.

No imports of natural gas from Canada or Mexico were reported during 1941. Exports to Mexico increased 30 percent over 1940 to about 7,100 million cubic feet, highest since 1936. The small volume of natural gas piped to Canada in the form of mixed gas was about 121 million cubic feet in 1941, up from 90 million in 1940.

[5] Exclusive of oil- and gas-field operators.
[6] Exceeds 100 percent, as part of the natural gas treated for natural gasoline is not marketed.

The number of consumers of natural gas increased 4 percent over 1939 to a total of 10,027,000 in 1940. More meters were reported in each of the 34 States in which natural gas is sold and in the District of Columbia. By the end of 1941 the number of meters served with natural gas had risen to at least 10,400,000.

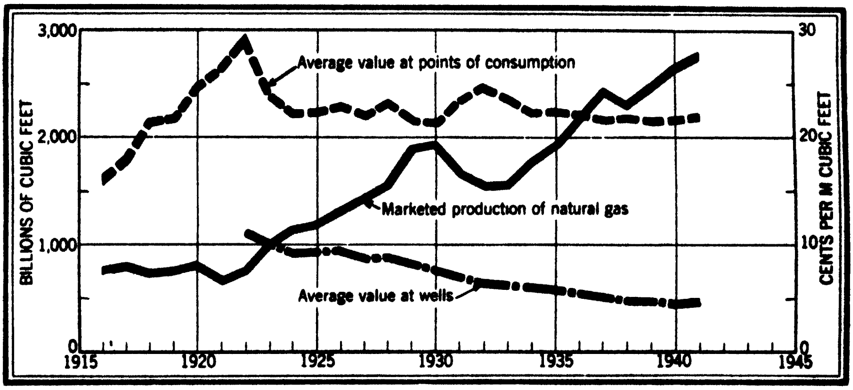

FIGURE 1.—Production and value of natural gas in the United States, 1916–41.

LEGISLATIVE AND LEGAL REVIEW

A natural-gas and natural-gasoline section was set up in the Office of the Petroleum Coordinator for National Defense on October 23, 1941. Its purposes are to integrate the activities of the gas industry in production, transportation, and distribution so as to serve the needs of a dynamic war economy effectively and to eliminate wasteful or nonessential use by the industry of critical materials, particularly steel.

Five district offices were opened, corresponding to those previously established for the petroleum industry, and surveys were begun in each district to determine the supply-and-demand situation and the problems to be anticipated. On December 23, 1941, General Preference Order M–68 was issued providing for acquisition of materials and supplies by oil and gas operators who comply with operating restrictions set up by the Petroleum Coordinator. The spacing pattern prescribed for gas wells was one well to each 640 surface acres of land. The immediate effect of this order was to curtail development work sharply in some currently active fields, but wildcatting did not seem to have been affected. The 640-acre-per-well rule was relaxed later in certain shallow producing areas where closer spacing had been common practice.

An amendment to the Natural Gas Act was signed by the President on February 7, 1942, broadening the jurisdiction of the Federal Power Commission over construction of natural-gas lines. Henceforth the approval of the Commission must be obtained before new gas-transmission lines are laid, whether or not the territory to be entered is already served by a natural-gas company.

The Commission was also given great power over gas rates by an important decision of the United States Supreme Court rendered March 16, 1942. It provides that property valuation, a focus of contention for many years, is no longer required as a basis for making

natural-gas rates. The "prudent investment theory" or others may now be used, and courts are directed in future not to set aside rates that are reasonable and on which fair hearings have been held by regulatory bodies.

GROSS PRODUCTION

In 1940 the estimated gross production of natural gas (3,694,100 million cubic feet) was 11 percent above 1939. Continued sharp gains in Texas and Illinois supplied most of the increased volume, with West Virginia, Louisiana, and Arkansas contributing materially. Notable declines occurred in New Mexico, New York, and Mississippi, the last two being caused by shortages of supply.

Reported gas production from gas wells increased 40 percent from 1935 to 1940; the trend was dominated by marked expansion in Texas and lesser growth in West Virginia, Louisiana, Kansas, and California. The recorded gas output of oil wells increased more rapidly in this interval, gaining 59 percent. The exploitation of large fields with high gas : oil ratios in Illinois, Louisiana, New Mexico, and Texas was the chief stimulus to this type of gas production.

The principal change in repressuring and pressure-maintenance operations in recent years is ascribed to the spectacular advance of the cycling process in Texas condensate fields, as indicated by volume data on Texas gas used for repressuring. It was as follows in cubic feet: 1938, 20 billion; 1939, 105 billion; and 1940, 294 billion. Similar activities in Louisiana are beginning to produce a pronounced upward trend there also. In California and Oklahoma the largest gas-repressuring volume was reported in 1935, but declining trends have persisted in both States since that year.

The volume of gas reported annually as stored in depleted natural reservoirs for future use has been relatively constant since 1935, averaging about 12 billion cubic feet a year. However, storage in 1940 was almost double the low volume of 1939 as the Appalachian States made sharp increases. Availability of numerous suitable fields in this region is a great aid to gas companies in meeting the winter peaks in demand and permitting longer-term storage.

The apparent loss and waste of gas decreased slightly in 1940, dropping to 655,967 million cubic feet, or 18 percent of the estimated gross production. Large reductions were shown in Louisiana, New Mexico, and Texas. Waste of gas in Illinois became important in 1938, with the new flush oil development, and increased rapidly throughout 1940 in the absence of State regulation.

Gross production and disposition of natural gas in the United States, 1939–40, by States, in millions of cubic feet

[1] Marketed production plus quantities used in repressuring, stored in ground, lost and wasted (see footnote 2).
[2] Includes gas (mostly residue gas) blown to the air, shrinkage at natural-gasoline plants, and transportation losses but does not include direct waste on producing properties, except where data are available.
[3] Produced approximately as follows: 220 million cubic feet in Texas, 122 million in Oklahoma, and 83 million in Kansas.
[4] Produced approximately as follows: 86 million cubic feet in Kentucky, 4 million in Pennsylvania, 406 million in West Virginia, and 191 million in Ohio.
[5] Produced approximately as follows: 227 million cubic feet in New York, 444 million in Pennsylvania, 128 million in West Virginia, and 32 million in Kentucky.
[6] Produced approximately as follows: 58 million cubic feet in Kentucky and 48 million in West Virginia.
[7] North Dakota, South Dakota, Tennessee, Utah, Virginia, and Washington.
[8] Subject to revision.
[9] Produced approximately as follows: 373 million cubic feet in Oklahoma, 525 million in Texas, and 264 million in Kansas.
[10] Produced approximately as follows: 183 million cubic feet in West Virginia and 300 million in Kentucky.
[11] Produced approximately as follows: 109 million cubic feet in Pennsylvania and 305 million in New York.
[12] Produced approximately as follows: 397 million cubic feet in Kentucky, 2,216 million in West Virginia, and 1,093 million in Ohio.
[13] Produced approximately as follows: 178 million cubic feet in Kentucky, 424 million in West Virginia, and 1,121 million in Pennsylvania.
[14] Produced approximately as follows: 148 million cubic feet in Kentucky, 7 million in Pennsylvania, and 271 million in West Virginia.

MARKETED PRODUCTION

A new peak in marketed production of natural gas was attained in 1941—an estimated total of 2,770 billion cubic feet, 4 percent above 1940. Larger output from producing States was general, but Louisiana apparently made the greatest gain. Production in Oklahoma declined slightly, and that of Mississippi and of New York fell sharply as available gas reserves continued to shrink, lacking the stimulus of substantial new discoveries.

Final 1940 data show expansion of output in all producing States except Mississippi, New York, Pennsylvania, and the "Other" group of small producers. New York reached a sharp peak in gas production in 1938 and Mississippi in 1939, followed by unusually abrupt declines.

Natural gas produced in the United States and delivered to consumers, 1936–40, by States, in millions of cubic feet

The average value of natural gas at the wells, which has been falling steadily for many years, reached a new low in 1940 at 4.5 cents per thousand cubic feet. Contributing to this decline have been reductions in average sales prices for gas in the field in nearly all producing districts and—of perhaps greater influence—the shift in location of the chief sources of gas supply from the old eastern fields to the Southwest, where unit costs of producing gas are much lower. Suggestive of these two processes are the following data: In 1928 the Appalachian States as a group sold 22 percent of the total marketed production of natural gas in the United States at an average wellhead value of 21.1 cents per thousand cubic feet. The principal southwestern gas-producing States marketed 57 percent of the total for the United States at a corresponding average of 4.7 cents per thousand cubic feet. In 1940 the same State groups marketed 15 and 68 percent, respectively, of the total at average values at the wells of 14.8 and 2.1 cents per thousand cubic feet.

[5] Includes 4,788,000 M cubic feet piped to Mexico.

WELLS

Reported completions (2,911) of gas wells in 1941 were 22 percent larger than the 1940 total and exceeded the number reported in the previous peak years of 1937 and 1929. Operators throughout the Appalachian region stepped up their drilling sharply as actual and prospective requirements threatened to tax all developed producing capacity. The increase in Appalachian completions approximated that of the entire country, as minor gains and losses in other districts about balanced each other.

The total number of producing gas wells on December 31, 1940, increased slightly over that on the corresponding date in 1939 to 53,880. Indicated abandonments of gas wells in 1940 were 2,032 a reduction

from 2,385 in 1939. Reports indicate that in recent years abandonments of old gas wells have exceeded total gas completions in the United States; thus, on December 31, 1930, 55,020 gas wells were reported, indicating that in the past decade 1,140 more gas wells have been abandoned than have been drilled.

Gas wells in the United States, 1939–41, by States

State	Producing Dec. 31, 1939	Drilled during 1940 [1]	Producing Dec. 31, 1940	Drilled during 1941 [1]

TECHNOLOGIC DEVELOPMENTS

War needs have caused rapid developments in the use of natural gas and its liquefied gases as constituents in the production of an ever-growing list of essential chemicals. Many well-known substances that have long been made from other source materials—for example, ammonia, ammonium nitrate, acetylene, certain anesthetics, and alcohols—are now being, or soon will be, produced in quantity by processing the ligher hydrocarbons associated with petroleum. In addition, entirely new compounds frequently are developed and put to use. Valuable new explosives, for instance, have been produced by nitration of methane and synthesis of nitro-hydroxy compounds.

An interesting process for dehydrating alfalfa has been developed in Kansas. It is preferable to sun drying because it preserves the vitamin A content by preventing the destruction of carotin, a carbohydrate from which vitamin A is derived. The dehydration of vegetables by natural-gas heat is growing rapidly in California and promises to spread to other States. The shortage of transportation facilities, particularly shipping, resulting from the war is an active stimulant to use of foods that are dehydrated before shipment, reducing both the tonnage and bulk to be moved.

Few people apparently have realized until recently the extent to which the efficiency of gas pipe-lines has been reduced by corrosion and accumulation of dirt inside pipes. A few experimental runs were

made with scrapers adapted from types commonly used in cleaning the interior of oil and gasoline lines. A surprising quantity of debris and miscellaneous scrap metal was brought out; in consequence, the effective capacity of the pipe was increased materially. Systematic cleaning programs, as carried out by one large gas company in Texas during 1940 and 1941, have improved line efficiencies 15 to 25 percent. A much wider use of cleaning devices for the interior of gas lines is anticipated when the design of scrapers and the techniques of using them are improved further.

Two circumstances are thought to have fostered for some years comparative neglect of gas pipe-line interiors by tending to mask true performance characteristics. First, the old formula that has been used most widely in calculating pipe-line capacity is now recognized as inaccurate for high-pressure lines in that it indicates line capacity materially below actual for clean pipe. Second, few large gas lines operate at or near maximum capacity in actual practice, except for brief periods of peak gas demand. Therefore, opportunities to observe line performance under conditions of stress are neither frequent nor prolonged.

REVIEW OF FIELD DEVELOPMENTS BY STATES

Arkansas.—Records of the Arkansas Department of Revenue indicate that natural-gas production in Arkansas in 1941 was 24,617 million cubic feet, a 10-percent increase over 1940. Output of the dry-gas fields in the northwestern district increased 18 percent to 6,384 million cubic feet and that of the southern fields 7 percent to 18,233 million cubic feet.

Important new markets for Arkansas natural gas will be provided by industrial plants projected under the war-production program at Malvern, Benton, Little Rock, and Pine Bluff. The new gas load is expected to exceed 150 million cubic feet daily and will be obtained chiefly from the McKamie, Macedonia, and Dorcheat fields, whose combined gas reserves exceed 400 billion cubic feet.

Treating plants are under construction that will remove the sulfur and liquids from the gas efficiently before it enters transmission lines. About 200 tons a day of marketable sulfur will be recovered as a by-product, as well as 70,000 or more gallons a day of natural gasoline and liquefied petroleum gases.

Two discovery wells that produced gas and condensate were reported in 1941. In July the Macedonia field, Columbia County, was opened in sec. 16, T. 18 S., R. 21 W. by No. 1 Franks, which produced 330 barrels of condensate with gas from the Smackover limestone at 8,906 to 8,914 feet. The Patton field, Lafayette County, was discovered in November, when No. 1 Moore, in sec. 29, T. 17 S., R. 24 W., found 215 barrels a day of condensate with gas at 9,312 to 9,340 feet in the Smackover limestone.

Four condensate wells were completed in the Macedonia field in 1941, 11 at McKamie, and 2 at Dorcheat. One gas well was reported in sec. 3, T. 18 S., R. 13 W., Union County, which had a daily capacity of 20 million cubic feet from a depth of 3,569 feet. Only two gas completions were listed in the northwestern counties. One of these, in the Alma field, Crawford County, sec. 6, T. 9 N., R. 30 W., was drilled to 6,578 feet; the other, in sec. 31, T. 10 N., R. 26 W., Franklin

County, was completed for 12 million cubic feet a day from a total depth of 1,717 feet.

Repressuring with gas of the Jones oil sand in the Shuler field began in 1941 under a unit operating agreement fostered by the State regulatory authorities. By this means gas will be conserved, and recoverable oil reserves are expected to be increased materially.

California.—For the first half of 1941 marketed production of natural gas in California was 184,554 million cubic feet, a 7-percent increase over the comparable 1940 period. The source of information is a report from E. F. McNaughton, California Railroad Commission. The volume of gas reported blown to the air—17.1 billion cubic feet during the first half of 1940—was reduced to 7.3 billion for the similar period in 1941 after the peak of flush oil production at Montebello had passed.

Discoveries in 1941 included three oil fields with relatively high gas : oil ratios—Raisin City and Riverdale in Fresno County and Helms in Kings County. Large gas reserves were proved at Raisin City. A new dry-gas field of undetermined importance was discovered 12 miles southeast of the Tracy gas field, San Joaquin County, The gas comes from a thin sand at relatively shallow depth. Several new productive zones were discovered in fields throughout the State. The Paloma gas and "condensate" field was extended west and southeast. On March 24 all producing wells in this field except dry-gas wells were shut in to eliminate excessive waste of gas and pressure drop pending adoption of a unit plan of operation for gas injection and pressure maintenance. The wells were still shut in at the end of 1941.

In the Cole's Levee field important gas production was developed in 1941 about 3,000 feet above the oil-producing formation. Gas-utility pipe lines are conveniently near this field.

Completions in gas fields during 1941 numbered 18, of which 14 were at Rio Vista, 2 at Vernalis, 1 at McDonald Island, and 1 at Delano. In addition, 3 gas wells were reported at Cole's Levee, 1 at Union Avenue, 1 at Elwood, and 1 at Santa Fe Springs oil fields.

All rights to the La Goleta gas field were acquired in 1941 by a utility company. Large compressor units and other equipment were installed to prepare the field for use as a gas storage reservoir.

The increased demand for gas resulting from war activities has strained the capacity of some gas producing and transmission facilities. To guard against critical shortages of gas, the California Railroad Commission instituted a general investigation covering the State gas reserves, consumers' requirements and the ability to meet them, and the economic factors relating to industrial use of gas as opposed to oil or other fuels.

Colorado.—Natural-gas production continued to expand in 1941 to 2,713 million cubic feet—30 percent above the 1940 output. The data are taken from a report by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. Withdrawals from the Powder Wash field were begun in June 1941 after an outlet was provided by laying an 8-inch line connecting with the Salt Lake City transmission system in the Hiawatha field.

The Powder Wash production was 477.3 million cubic feet. Hiawatha and Thornburg production increased to 1,996.6 and 114.2 million cubic feet, respectively. The output of other fields declined and was as follows, in millions of cubic feet: Berthoud 50.4, Craig

4.2, and Garcia 70.2. Small amounts of gas were used in the field, and 110.3 million cubic feet were estimated to have been wasted in connection with the production of oil in the Wilson Creek field.

Four gas wells were completed in 1941, with a total daily initial capacity of 30.1 million cubic feet; two of these were at Powder Wash and two at Hiawatha.

Illinois.—Natural gas produced and marketed, exclusive of that used for field purposes, increased 46 percent to 1,699.4 million cubic feet in 1941, as reported by A. H. Bell and G. V. Cohee, Illinois Geological Survey, Urbana, Ill. The gas was produced in five fields, as follows: Russellville and Ayers gas fields, 863 and 13.4 million cubic feet, respectively; and Salem, Louden, and Albion oil fields, 165, 536, and 122 million cubic feet, respectively. The Salem and Louden gas is residue from gasoline plants.

Eight new gas wells were drilled in the Russellville gas field during 1941, and one was abandoned, leaving 48 active. The productive area of the Buchanan sand is about 1,600 acres and of the Bridgeport sand 260 acres. The initial daily production of the new wells averaged about 2 million cubic feet.

Estimated gas production of the Louden pool during 1941 was 13.7 billion cubic feet, and the daily average at the end of the year was about 36 million. Two gasoline plants process 15 million cubic feet daily, and 6 million cubic feet of residue gas are injected into the oil-producing sands. A line to St. Elmo and Brownstown takes about 1.4 million cubic feet of residue gas a day.

Salem-field gas production during 1941 is estimated to be 35.4 billion cubic feet, and production was about 82 million cubic feet daily at the end of the year. Three gasoline plants process 59 million cubic feet a day, of which 4 million cubic feet are returned to oil sands and 1 million used in Salem, Centralia, and Mount Vernon.

The Centralia field produced only 1.8 billion cubic feet of gas during 1941, the daily output having declined to about 4 million cubic feet in December; about 100,000 cubic feet a day were being returned to producing formations.

In the Storms field, the daily rate of gas production had declined 95 percent in 2 years to 5 million cubic feet at the end of 1941. Estimated 1941 output of gas was 2.2 billion cubic feet. Injection of 120,000 cubic feet a day was begun during 1941.

The New Harmony, Griffin (Indiana), and Keensburg oil fields produced an estimated 9 billion cubic feet of gas in 1941, the daily production being about 25 million cubic feet. A gasoline plant under construction is designed to take 20 million a day of this gas, and it is planned to return the residue gas to producing sands.

The Albion pool, Edwards County, now making about 1 million cubic feet of gas a day, produced about 445 million cubic feet in 1941, part of which was sold to a brick plant at Albion.

A group of fields of the Central Basin area in Jasper, Richland, Clay, Wayne, northern Hamilton, and northwestern White Counties increased their estimated gas output to 24.5 billion cubic feet during 1941. The new Johnsonville field, Wayne County, supplies more than one-third of this volume.

The fields on the south and southwest margin of the Illinois Basin in southern Illinois produced an estimated 14.5 billion cubic feet of gas. These include, among others, the more important producing

pools, such as Woodlawn, Jefferson County; Benton, Franklin County; and Rural Hill, Hoodville, and Dale, Hamilton County.

Indiana.—Production of natural gas increased 9 percent in 1941 to 1,355 million cubic feet, chiefly in consequence of new supplies from the North Glendale field discovered in 1941 in southern Daviess County and from old wells in the Unionville gas field, Monroe County, which had been shut in since discovery. Information is taken from a report by Robert G. Reno, State gas supervisor, Indianapolis.

The North Glendale field was discovered in sec. 16, T. 2 N., R. 6 W., in June 1941 by the McCracken No. 1, which produced one-half million cubic feet a day from the Cypress sand at 728 to 735 feet. Seven gas wells were completed by the end of 1941. An isolated gas well was completed in the old, abandoned, Francisville field in southern Pulaski County. It made one-half million cubic feet, with a rock pressure of 155 pounds. No other gas wells have been completed in the area.

Gas completions fell from 77 in 1940 to 56 in 1941 owing to the sharp decline in drilling in the Rockport field, which was largely drilled up in 1940. Development work in the Old Trenton area increased. Four additional Trenton wells were completed in the Unionport field, Randolph County—a 1940 discovery—and the field began producing about one-half million cubic feet of gas a day commercially in the latter part of 1941. Gas-well completions, by fields, included: Buffkin 1 (no market), Greensburg 12, North Glendale 7, Iva 2, Harrison County 6, Loogootee 1, Merom-Raley 3, Oatsville 1, Rockport 3, Unionville 1, Unionport 4, Veale 1, and Old Trenton (many counties) 13.

Gas production from most fields decreased moderately in 1941, although rather sharp declines were reported from the Harrison County and Troy-Tell City fields. The Rockport field, which now supplies about one-third of the Indiana gas production, increased its output 17 percent in 1941. Production in 1941, by fields, in millions of cubic feet was: Alford 60, Francisco 4.5, Greensburg 177.9, Harrison County 100, Hudsonville (including North Glendale) 31, Loogootee 5, Oaktown 96.6, Rockport 461, Shelburn-Grayville 33.9, Old Trenton (including Randolph County) 200, Troy-Tell City 1.5.

The Harmon gas field was abandoned in 1941 after 12 years of production. The Troy-Tell City field is almost depleted and probably will be abandoned in 1942.

Kansas.—Marketed production of natural gas in Kansas increased 10 percent in 1941 to about 99 billion cubic feet. Although small declines in output of most fields were the rule, a few large fields—notably Cunningham, Hugoton, and Thurber—had sharp increases, according to the Kansas Corporation Commission records. The McLouth field in Jefferson and Leavenworth Counties, which did not produce during 1940, had an output of 1,667 million cubic feet in 1941. The more important gas-producing fields were drawn upon for the following volumes during 1941, in billions of cubic feet: Hugoton 36.4, Cunningham 18.0, Otis 9.0, Medicine Lodge 7.1, Burrton 4.5, McPherson County 4.2, Thurber 3.4, and Lyons 2.4.

According to a report by R. P. Keroher, Kansas Geological Survey, 102 gas wells were reported in 1941—52 in eastern Kansas and 50 in the western part. Thirteen of the western wells and three of the eastern made oil with the gas.

Seven gas discoveries were reported, of which only one was in the eastern part of the State—the Robinson pool, Marion County, in sec. 15, T. 20 S., R. 5 E., where one well found gas in sand in the lower Cherokee formation. New gas wells were reported in certain eastern counties, including Cowley, Greenwood, Jefferson, Leavenworth, and Johnson. Development of the McLouth pool, a 1939 discovery, in Jefferson and Leavenworth Counties, was much the most important gas activity in eastern Kansas. A total daily potential of 260.6 million cubic feet was obtained from 39 wells.

Western Kansas discoveries were the Bergtal (sec. 22, T. 20 S., R. 15 W.) and Krukenberg (sec. 11, T. 19 S., R. 15 W.) pools in Barton County, the Zook (sec. 16, T. 23 S., R. 16 W.) pool in Pawnee County, the Preston (sec. 18, T. 26 S., R. 11 W.) and Ward (sec. 11, T. 26 S., R. 12 W.) pools in Pratt County, and the Hitz (sec. 4, T. 24 S., R. 12 W.) pool in Stafford County. The Bergtal and Zook pools produce from the Arbuckle limestone; the Krukenberg from the Lamotte sand; and the Preston, Ward, and Hitz pools from the Viola limestone.

New production was developed in old fields as follows: Otis pool had three wells with 24.6 million cubic feet of daily potential; Rick pool, one new well good for 1.8 million; Silica, two wells with 5.2 million; Kipp, two small wells; Zenith, three wells with 8.8 million; Medicine Lodge, one well with 22.8 million; Orth, one well with 38.4 million; and Thurber, three wells with 38.4 million. In the Cunningham-Cairo district of Kingman and Pratt Counties, 16 new wells were drilled, with a total daily capacity of 190.5 million cubic feet. Three of these were old wells that found deeper production. In the Hugoton field a daily potential of 184.1 million cubic feet was developed from 11 new wells.

According to available reports, which are not complete, the total daily potential of gas brought in during 1941 was 825.4 million cubic feet, of which 33 percent (276.7 million cubic feet) was in eastern Kansas. This represents a considerable decline in total new capacity from 1940, despite a sixfold increase in eastern counties owing to the exceptional McLouth-pool development.

Kentucky.—Drilling for gas in eastern Kentucky, particularly in the Big Sandy area, was about 100 percent more active in 1941 than in 1940 because of the growing need for gas in industrial districts to the north and east. A total of 233 gas wells was reported compared with 113 in 1940. The most active counties, with the number of gas-well completions, were: Floyd 65, Pike 72, Knott 45, Martin 32, and Johnson 14. In western Kentucky, 23 gas completions were reported in 1941 compared with 12 in 1940; 3 were in Ohio County, 2 in Muhlenberg, 2 in Daviess, 5 in Clay, 4 in Jackson, 4 in Knox, and 3 in Clinton.

Marketed production of Kentucky gas is estimated to have increased 12 percent in 1941 over 1940, owing chiefly to increased movement into West Virginia and Ohio.

A new gas field producing from the Big Six sand was opened in Johnson County 4 miles west of Paintsville. Extensions of gas-producing areas were made in Pike and Knott Counties.

In 1941 four deep tests to the Knox dolomite (Cambro-Ordovician) were completed in eastern Kentucky; all were failures. These wells were in Magoffin County on the Paint Creek uplift, in Elliott County on the Burke dome, in Laurel County on the Sinking Creek dome, and in Clark County in the Ruckerville fault area.

Louisiana.—In north Louisiana, gas-well completions in 1941 increased to 93, or 24 percent. Forty-eight of these were in the Monroe gas field, and the remainder were scattered. Reported gas completions in south Louisiana totaled 12 in 1940 and 18 in 1941. The producing formation at Monroe has been extensively treated with acid in recent years resulting in the satisfactory revival of many old wells of low current capacity.

Four gas discoveries were reported in northern Louisiana in 1941. Of possible wide significance was the finding of commercial quantities of oil or gas in the Smackover limestone for the first time in Louisiana. The discovery well was No. 1-A Meadows in the Lisbon field, Claiborne Parish, which was completed as a gas and condensate well from 10,148 to 10,398 feet. In sec. 36, T. 12 N., R. 3 E., Caldwell Parish, the No. 1 Lowe made 15 million cubic feet of gas from the Wilcox formation at 2,173 to 2,178 feet, after being plugged back from 4,009 feet. Three miles northwest of Lisbon, in sec. 11, T. 21 N., R. 4 W., the No. 1 Alford opened a new area when it produced 5 million cubic feet of gas and 80 barrels of condensate a day from the Pettit lime at 5,098 to 5,112 feet. A shallow discovery, in the Eocene at 1,462 to 1,465 feet, was made by No. 1 Hughes in sec. 22, T. 8 N., R. 1 E., La Salle Parish, good for 10 million cubic feet of gas after it had been plugged back from the Wilcox at 4,092 feet total depth.

In the Louisiana Gulf Coast section eight discoveries, all from the Miocene, were reported—one dry gas and seven condensate producers. The gas discovery, Bay Decherre in La Fourche Parish, was shallow (2,460 to 2,528 feet), but all the condensate wells were deep, producing at 6,750 to 10,883 feet. The latter were: Point Aufer and Lapeyrouse, Terrebonne Parish; Belle Isle, St. Mary's Parish; De Lacrois Island, Plaquemines Parish; Lakeside and Pecan Lake, Cameron Parish; and Lewisburg, Acadia Parish.

Records of the Louisiana Department of Minerals indicate that gross measured gas production in 1941 was 574.8 billion cubic feet—375.1 billion from gas wells and 199.7 billion from oil wells. North Louisiana produced 333.3 billion cubic feet from gas wells and 66.0 billion from oil wells. South Louisiana produced 41.8 billion from gas wells and 133.7 billion from oil wells. Gas processed for gasoline extraction rose from 145.2 billion cubic feet in 1940 to an estimated 250 billion in 1941. Several pipe-line construction projects increased the facilities for transporting Louisiana gas to important markets in other States during 1941.

About 55 billion cubic feet of gas were returned to producing formations in pressure-maintenance operations during 1941, or more than double the volume in any previous year. Three major projects were operating—at Tepetate, Ville Platte, and Cotton Valley—in addition to small ones. The cooperative installation at Cotton Valley is the largest in existence, having a rated daily capacity of 150 million cubic feet of gas. It started operating in July 1941. Liquid-product production is expected to exceed 10,500 barrels a day.

A fourth large pressure maintenance project, at South Jennings, Jefferson Davis Parish, began operating during the last week of 1941.

Michigan.—Reported natural-gas production reached a new high of 15,092 million cubic feet in 1941, or 6 percent more than in 1940, according to information from F. R. Frye, petroleum engineer, Michigan Department of Conservation.

In all, 97 gas wells were drilled, more than in any year since 1936. Activity was due chiefly to the development of fields discovered in 1940 and to the discovery and partial development of the Deerfield pool in western Isabella County—an extension of the old Broomfield pool. The discovery well—Winesburg No. 1, sec. 20, T. 14 N., R. 5 W.—was completed in March 1941 for 2.2 million cubic feet of ga. a day from the Michigan Stray sand at 1,292 feet. Twelve wells drilled in 1941 provided 2,000 acres for production. Further development is expected. Six wells were drilled in the Broomfield pool.

The Reed City gas field, Osceola County, discovered in November 1940, was expanded to cover 4,100 acres by drilling 24 gas wells. Production is from the Michigan Stray sand at 1,150 to 1,250 feet.

Sixteen gas wells were completed in the Marion gas field, Clare and Osceola Counties. Proved territory covers about 5,000 acres. Five wells were added to the Riverside pool, Missaukee County, increasing its probable productive area to 1,600 acres.

The Bateson No. 1 test in sec. 2, T. 14 N., R. 4 E., Bay County, which blew out in 1940 with a heavy flow of wet gas from 7,776 feet, was deepened to a record 10,445 feet. It penetrated the St. Peter sandstone but being dry in the deeper zones was plugged back to 7,800 feet and completed as a gas and "condensate" well.

In the Salem field, Allegan County, the Heasley No. 1 in sec. 21, T. 4 N., R. 13 W., was completed as a gas well in the Salina formation at 3,792 feet. Open-flow capacity was 304,000 cubic feet and closed pressure 1,150 pounds. The Evart gas pool was discovered in November 1941 by Wirth No. 1 in sec. 22, T. 18 N., R. 8 W., Osceola County. It made 388,000 cubic feet from the Michigan Stray sand at 1,467 feet. Two additional wells were drilled in 1941.

A well in sec. 7, T. 18 N., R. 7 W., Osceola County, found 1.9 million cubic feet of gas in the Michigan Stray sand at 1,528 feet to open a new producing area. A second well was drilled in 1941.

Four Berea-sand gas wells completed in the Deep River pool in Arenac County at 1,500 to 1,550 feet proved an area of about 800 acres. The largest of these wells made 3.5 million cubic feet a day.

Perhaps the most important gas discovery of 1941 was made by Turner No. 1 in sec. 15, T. 3 S., R. 4 W., Calhoun County, 60 miles from the nearest gas well. A reported daily flow of 10.5 million cubic feet was found in Traverse limestone at 1,609 feet. Closed pressure was about 720 pounds.

Mississippi.—At the end of 1941 the Jackson gas field had 23 producing wells; all but 5 were producing some salt water with the gas. Total gas production in 1941 was 3,878 million cubic feet, a reduction of 39 percent from 1940, according to information supplied by H. M. Morse, supervisor of the Mississippi State Oil and Gas Board.

Of five wells drilled on the Jackson structure during 1941, four were completed as gas wells and one was a dry hole. In addition, a 1940 dry hole was completed as a gas well in January 1941 after it blew in from a depth of about 1,100 feet while casing was being pulled. Nine wells in the field were abandoned during 1941.

The Jackson field continued to yield the only commercial gas production in Mississippi. Casinghead-gas production in the Tinsley oil field is negligible; in fact, gas is piped in for fuel.

Missouri.—Information from Frank C. Greene, geologist, Missouri

Geological Survey, indicates that gas completions and new capacity fell off sharply in 1941 from the 1940 totals. Of the 18 gas wells drilled, 9 were in the Polo field, Caldwell County (a 1940 discovery), and had a total daily open-flow capacity of 4.4 million cubic feet. The Prairie Point field, Platte County, had 5 new wells with total daily capacity of 7.9 million cubic feet; 4 small wells were drilled in Jackson County. No new gas areas were opened.

Montana.—Completion of 59 gas wells in 1941 marked a continued expansion in gas development since the low point in 1938, when only 21 were reported. A report by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo., is the source of information. Only one new well was in wildcat territory; drilled in sec. 18, T. 35 N., R. 4 E., Liberty County, it opened the Haystack Butte field in November 1941, when it flowed 1.3 million cubic feet of gas a day from two sands in the Colorado shale at 1,938 and 2,162 feet.

Twenty-nine wells were drilled at Bowdoin to comply with lease agreements and to prepare for unitization of the field. The Kevin-Sunburst area had 9 gas completions; Cedar Creek had 7. The remainder of the new wells were scattered in other fields.

Marketed production increased 7 percent in 1941 to 27,319,244,000 cubic feet. Production of the Bowdoin field more than doubled, as it supplied a substantial portion of the gas requirements of the pipeline system formerly dependent on Cedar Creek alone. Cedar Creek withdrawals were reduced 12 percent to conserve its gas reserve for future peak loads. The production rates of other fields did not change radically from 1940. It is estimated that 13,214 million cubic feet of gas were used for domestic and commercial purposes (increase, 14 percent) and 14,152 million for industrial purposes (increase, 1 percent).

The two active gasoline plants in Montana processed 7 percent more gas in 1941 than in 1940. The absorption plant at Cut Bank handled 10,565 million cubic feet, from which it extracted over 4 million gallons of natural gasoline and liquefied gases. At the Dry Creek plant, 200 million cubic feet of gas were processed and 59,000 gallons of natural gasoline recovered.

Number of wells and natural gas produced in Montana in 1941, by fields

Field	Number of wells producing gas Dec 31, 1941 [1]	Marketed gas production (M cubic feet) [2]	Gas used for repressuring (M cubic feet) [2]	Estimated field use (M cubic feet) [2]	Estimated waste (M cubic feet) [2]
Bowdoin	93	2,334,855		500	2,000
Bowes	13	577,240			1,000
Box Elder	7	479,393			500
Cedar Creek	159	6,642,516			10,000
Cut Bank	87	11,426,478			100,000
Devon	9	310,664			500
Dry Creek	6	1,060,381			2,000
Hardin	61	82,071			800
Haystack Butte	1	13,152			1,500
Kevin-Sunburst	190	3,408,472	7,200	20,000	18,250
Whitlash	17	984,022			100
Total Montana	643	27,319,244	7,200	20,500	136,650

[1] Compiled by Oil Conservation Board of Montana.
[2] Data supplied by L. G. Snow, acting supervisor, Geological Survey, U. S. Department of the Interior.

New Mexico.—Gas-well completions in southeastern New Mexico in 1941 about doubled the 1940 record in both number and initial capacity, according to information supplied by Foster Morrell, acting supervisor, Geological Survey, United States Department of the Interior, Roswell, N. Mex. Thirteen wells had a total initial daily production of 158.5 million cubic feet.

Gas marketed from the Lea and Eddy County fields totaled 36,472 million cubic feet, 30 percent above the 1940 total. Only about 1 percent of this gas came from Eddy County. The throughput of gasoline plants was 109,756 million cubic feet, a 13-percent gain over 1940. Gas lift, other oil-field uses, and venting without gasoline-plant treatment are estimated to have consumed 19,289 million cubic feet. About 50 billion cubic feet of residue gas presumably were blown to the air. One gas pipe-line company has arranged to market increased volumes of residue gas in future.

A shallow gas discovery was reported in Eddy County in August. The No. 1 Willis in sec. 14, T. 20 S., R. 28 E., made 3 million cubic feet of gas from the Permian at 830 to 930 feet.

In the northwestern part of the State, six gas wells were drilled in 1941 with a total initial capacity of 10.4 million cubic feet. Gas production was 28 percent larger than in 1940 and totaled 3,677 million cubic feet. The output of Fulger Basin increased severalfold in 1941 to 600 million cubic feet. Withdrawals from other fields increased moderately; Kutz Canyon produced 2,053 million cubic feet, Ute Dome 985 million, and Blanco 39 million.

New York.—Drilling for natural gas in the Oriskany sandstone obtained a smaller total of initial production during 1941 for the fourth successive year, according to information supplied by C. A. Hartnagel, State geologist. From a daily peak of 403.4 million cubic feet in 1937, the initial productive capacity has fallen to 91 million in 1941. Of 42 wells drilled in 1941, 18 were producers compared with 1940 totals of 50 and 20, respectively.

Allegany and Steuben Counties continued to lead in development, although Steuben replaced Allegany in 1941 as the area in which nearly all the substantial new production was found. Allegany County slipped badly from 13 wells with 84.6 million cubic feet initial capacity in 1940 to 2 wells with 8.3 million in 1941. Comparable data for Steuben County were 3 wells with 13.6 million cubic feet capacity in 1940 and 14 wells with 82.1 million in 1941. Half of the 42 Oriskany tests drilled during 1941 were in Steuben County. In Cameron Township all five of the wells drilled were successful, and their new daily production totaled 35.8 million cubic feet of gas. Three of five wells drilled in West Union Township came in with a total production of 39.3 million cubic feet. In Howard Township six wells drilled in 1941 were all small producers, but they are closely spaced and the life of the field may be short.

Other exploratory wells to the Oriskany sandstone were drilled in Tompkins, Chemung, and Wyoming Counties; of these, only two in the city of Elmira (Chemung County) gave production, and it was small. As a whole, the known fields producing from the Oriskany sandstone are being rapidly depleted; numerous tests during the last few years have failed to find any important new Oriskany pools. The Wayne-Dundee field, where gas from the Oriskany sandstone was discovered in 1930, is now being used for storage of gas.

North Dakota.—Natural-gas production has been unimportant in the past in North Dakota, but growing interest in exploration by oil companies may presage a more active future. Wilson M. Laird, State geologist, has furnished the following information.

Five gas wells were drilled in 1941 in a southeastern extension of the Cedar Creek (Mont.) field, in the extreme southwestern corner of the State. At the end of 1941, eight small gas wells on the North Dakota side of the State boundary were producing from the "Eagle" sand. They were shut in except for November and December, when 47 million cubic feet of gas were withdrawn. The gas is piped into Montana, where it enters the large pipe-line system that supplies parts of the Dakotas and eastern Montana.

In the Souris River gas area in the vicinity of Mohall, a number of small gas wells have produced for years from the Dakota sandstone, which occurs there at a depth of about 1,000 feet. The gas is used locally in a few homes, as the supply apparently is too small to encourage commercial exploitation. Small amounts of gas are also produced and used locally in an area near La Moure in the southeastern part of the State. It comes from the Dakota sandstone with artesian water.

Ohio.—A 27-percent increase in drilling during 1941 resulted in 43 percent more gas-well completions and a 72-percent increase in volume of initial gas capacity. These ratios indicate a fair degree of success for the intensive efforts to develop more gas in Ohio. Data are taken from a report by Kenneth Cottingham, chief geologist, Ohio Fuel Gas Co. The average initial capacity per well increased from 581,900 cubic feet in 1940 to 702,000 in 1941. Larger average wells were completed in all producing formations except the Trenton, in which activity was negligible.

The Clinton sand continued dominant as a source of gas, with 325 wells averaging 1,092 thousand cubic feet of gas a day. Gas completions in other sands, with average initial daily capacity in thousands of cubic feet, were: Shallow sands 162 with 381 average, Berea 150 with 188, Ohio shale 26 with 191, Oriskany 7 with 432, Newburg 29 with 1,356, and Trenton 2 with 50.

A total of 35 counties—five more than in 1940—reported gas-well completions in 1941. The most active counties, in order, were: Licking 102, Meigs 63, Athens 60, Washington 46, Muskingum 45, Knox 43, Noble 34, and Monroe 31. The sharpest gain in number of wells was in Meigs County.

Four deep tests were drilled through the Trenton limestone. A small show of gas was encountered in one of them in a sandy formation, called the St. Peter, at 3,975 feet in sec. 21, Jersey Township, Licking County.

Clinton-sand development was most active in Licking County, where 91 gas wells were completed, most of them in the area northeast of the city of Newark. Thirty-nine Clinton gas wells were drilled in Knox County and 45 in Muskingum. The largest well of the year in Ohio was Winters No. 1, in sec. 5, Salt Creek Township, Muskingum County, which made 12 million cubic feet from the Clinton sand at 4,123 feet and had a closed pressure of 1,120 pounds. Two other Clinton-sand wells in Muskingum County and two in Morgan County tested 10 million cubic feet or more initially. A Newburg-sand well in Independence Township, Cuyahoga County, yielded 6 million cubic feet a day from a depth of 2,720 feet.

In Washington Township, Harrison County, several Clinton wells were drilled; two of them made producers of 471,000 and 365,000 cubic feet of gas initial daily capacity from depths below 5,800 feet. Another deep well made 559,000 cubic feet of gas from the Clinton sand with total depth of 5,289 feet. It was drilled in sec. 26, Union Township, Tuscarawas County. A number of deep dry holes were drilled in eastern Ohio through the Oriskany or Clinton sands, the deepest going to the Clinton at 7,887 feet in sec. 19, Smith Township, Belmont County; this was the second-deepest hole ever drilled in Ohio.

Oklahoma.—Continued decline in production of natural gas from oil wells caused a 6-percent drop in gas production for 1941 to 254,881 million cubic feet, according to the Oklahoma Tax Commission. A 3-percent increase in production from gas wells to 90,529 million cubic feet was overbalanced by an 11-percent decline in casinghead gas output to 164,352 million cubic feet.

Although drilling for oil and gas increased moderately in Oklahoma in 1941, owing in part to a 30-percent increase in wildcatting ventures, gas-well completions apparently declined slightly to about 175 from about 180 in 1940. Most of the gas wells continued to be drilled in the old eastern areas, led by Muskogee, Okmulgee, Creek, Wagoner, Okfuskee, and Latimer Counties. Nine gas completions were reported in the Chickasha field and 5 at Cement, adding materially to productive capacity of these important fields. One well drilled in eastern Texas County increased the already vast area proved for gas production.

A total of 14 gas discoveries was reported—2 in the Wilcox sand, 3 in the Cromwell, and 1 each in 9 other formations above the Wilcox. By counties they were as follows: Hughes 2, Lincoln 2, Okfuskee 2, and 1 each in Carter, Le Flore, Osage, Pontotoc, Pottawatomie, Seminole, Stevens, and Texas. A new pay formation was found in the Centrahoma area of Coal County when a well in sec. 27, T. 2 N., R. 9 E., made 10.6 million cubic feet a day from a sand at a depth of 1,340 feet.

Gas output of the Oklahoma City field continued to shrink rapidly as pressures in several sands declined below pipe-line intake pressures. The oil operators who blew many billions of cubic feet of gas to the air to produce oil as rapidly as possible now regret the current absence of a vast quantity of natural gas at low prices such as would make repressuring profitable.

The volume of gas piped from Oklahoma fields to markets to the north and east probably was 10 percent larger in 1941 than in 1940, due chiefly to increased takings from the Chickasha-Cement district and from Texas County.

Pennsylvania.—The outstanding trend during 1941 in Pennsylvania gas fields was intensification of development in shallow-sand territory, according to information from J. G. Montgomery, Jr., vice president, United Natural Gas Co. This was the natural result of increased gas demand from war-stimulated industry and the foreshadowed exhaustion of the northern Oriskany sand fields.

The active drilling campaign resulted in several discoveries; the most important was probably the Armbrust pool in Westmoreland County, where about 600 acres were proved for Fifth-sand gas production, with the limits of the pool still undefined. Average initial open-flow capacity of the wells was 780,000 cubic feet and reservoir pressure

1,015 pounds at the year end. *Fifteen* wells had been completed by the end of 1941, and 24 more were being drilled.

In East Franklin and Sugar Creek Townships, Armstrong County, a small gas pool was discovered in the Hundred Foot sand. A Kane sand well in Oliver Township, Jefferson County, completed for an initial daily production of over 2 million cubic feet, spurred activity in that region. In western Fayette and eastern Greene Counties a number of wells with an initial daily open-flow capacity of 1 to 5 million cubic feet were completed in the Big Injun sand and Mississippian. A well in Forward Township, Allegheny County, made 9 million cubic feet a day from the Bayard sand of the Upper Devonian. The smaller capacity of wells drilled recently in the Sliverville pool, McKean County, formerly prolific in gas as well as oil, indicates that it is nearing exhaustion.

Commercial exploitation of gas from the shallow Portage shales of western Erie County was attempted. Initial daily volumes varied widely but averaged about 900,000 cubic feet.

Oriskany-sand development resulted in one small discovery and extension of the producing area of one field. The discovery well in Bingham Township, Potter County, made about 1 million cubic feet of gas a day from the Oriskany sand. Five scattered dry holes were drilled to this sand in the Potter-Tioga Counties district. The Summit gas pool, Fayette County, was extended 1 mile southwestward with the completion of three wells in South Union Township. Their initial daily capacities were 1, 2, and 3 million cubic feet from the Chert zone of the Onondaga formation and the underlying Oriskany sandstone. Three more wells were being drilled in the field. In Stewart Township the deepest test ever drilled in Pennsylvania shut down at 8,498 feet after encountering only 16,000 cubic feet of gas in the Oriskany.

Three Oriskany exploratory wells, drilled respectively in North Sewickley Township (Beaver County), Springfield Township (Mercer County), and West Franklin Township (Armstrong County), were completed as dry holes; the last two holes did not encounter the Oriskany sandstone. Other Oriskany tests were being drilled in Greene, Beaver, and Westmoreland Counties.

A small show of gas was found in the St. Peter sandstone in a well in Springfield Township, Erie County, which penetrated this formation in Pennsylvania for the first time.

Gas production from shallow sands increased greatly during 1941, whereas Oriskany-sand production from the Potter-Tioga Counties fields continued its decline from 6.5 billion cubic feet in 1940 to 3.75 billion in 1941.

Blow-outs due to high-pressure gas pockets in the Marcellus shale were overcome at the Beaver County Oriskany test by drilling a pilot hole ahead of the larger tools and then reaming. Other operators have carried a column of brine in the hole to combat this nuisance.

South Dakota.—No wells were drilled in South Dakota during 1941, according to information from E. P. Rothrock, State geologist. The small gas production at Pierre and Fort Pierre continued to be separated from artesian water and marketed locally.

Geological and geophysical prospecting by major oil companies continued in 1941. Large areas are under lease in central and extreme western South Dakota, and some wildcat drilling may be attempted in the spring of 1942.

Tennessee.—Kendall E. Born, assistant geologist, Department of Conservation, Nashville, Tenn., reports that natural gas is marketed from producing leases in two areas in Tennessee—Sunbright in northern Morgan County and Jamestown in Fentress County.

A small volume of gas is obtained from oil wells 5 miles northwest of Sunbright which produce from beds of lower Mississippian age at 1,150 to 1,400 feet. A 2-inch pipe line serves the small community.

Four shallow wells about 3 miles south of Jamestown produce gas from fractured limestones of Trenton age. The gas was piped into Jamestown about 2 years ago, but no production figures are available.

Texas.—Gross gas production in Texas continued its upward trend to new high levels in 1941 to total about 1,740 billion cubic feet, as estimated from incomplete State reports. Gas wells are thought to have produced about 1,200 billion and oil wells 540 billion cubic feet.

As in 1940, operations of cycling plants in condensate fields expanded rapidly (30 percent); about 420 billion cubic feet of gas were processed, accounting for the increase in gas-well output. During November and December 1941, recycling plants returned an average of 1,200 million cubic feet of gas a day to producing formations under high pressures, and the total daily intake volume of these plants slightly exceeded 1,400 million cubic feet. The average yield of petroleum liquids of all types from these plants was about 1.1 gallons per thousand cubic feet of gas processed. At the end of 1941, 280 producing wells were connected to recycling plants, an increase of 37 during the year.

Gas-well completions reported totaled 294 in 1941, an increase of 5 over 1940. Panhandle completions slumped from 81 in 1940 to 49 in 1941, and Eastern Texas completions were off slightly from 59 to 54. Modest gains were reported in other areas, led by Southwest Texas with 18 more gas wells to a total of 88 in 1941 and North Central Texas with a gain of 17 to 54.

In 1941, 23 gas and condensate discoveries were reported, comprising 8 condensate producers and 15 dry gas wells. The Eastern Texas district had 3 condensate discoveries—Pleasant Grove, Rusk County; Willow Springs, Gregg County; and Grosbeck, Limestone County. These fields produce from the Woodbine, Rodessa, and Pettit formations, respectively. In the Hawkins field, Wood County, a substantial gas reserve was indicated in the sub-Clarksville sand just above the Woodbine oil sand.

In North Texas a single gas discovery was made by No. 1 Mosely, which produced 2.2 million cubic feet of gas from the Bend series at 4,498 to 4,510 feet.

On the Gulf coast, condensate discoveries were reported at Needville in Fort Bend County and Vienna in Lavaca County, producing from the Frio and Wilcox formations. A gas area was opened at Navidad, Jackson County, by No. 1 Terrell, which found pay in the Frio at 3,786 to 3,793 feet.

Of seven discoveries listed in Southwest Texas, five produced from the Jackson formation. Two of these were condensate wells at Genevieve, Bee County, and Rios, Duval County. Dry gas discoveries were made at Chaparosa and East Colorado, Jim Hogg County, and Heard, Bee County. A Frio sand condensate discovery was made at Coloma Creek, Calhoun County; and at Steamboat Pass, also in Calhoun, a well made 32 million cubic feet of gas from the Catahoula at 2,880 to 2,885 feet.

In West Texas a wildcat produced 2 million cubic feet ot gas from a limestone at 1,250 feet at Baldwin in Menard County.

Eight dry-gas discoveries were reported in West Central Texas. Largest initial capacity was from the No. 1 Hendricks, which made 13 million cubic feet a day from the Cisco at 1,476 to 1,489 feet to open the Crites pool in Haskell County. In Stevens County an unnamed pool was opened by No. 1 Wheland, which made 10.5 million cubic feet of gas from the Marble Falls limestone at 4,077 to 4,095 feet, and the Loving pool was discovered by No. 1 Walls Pasture Co., which found 1.2 million cubic feet in the lower Caddo lime at 4,069 to 4,082 feet. Other discoveries were: Kirk pool in Eastland County and Greynolds pool in Brown County which produced from the Caddo lime, the Elliott pool in Shackelford County which made gas from the Canyon limestone, the Silver Valley pool in Coleman County which produced from the Fry sand (Strawn), and the Noland pool in Palo Pinto County which produced from the Strawn series.

Utah.—Production of natural gas increased 9 percent in 1941 to 4,705 million cubic feet, as reported by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. The Ashley Valley field, which furnished the only commercial gas production in Utah in addition to the Clay Basin field, was exhausted after producing only 15 million cubic feet in 1941. The wells were being abandoned and materials salvaged at the year end. The Last Chance gas field, with one well available, remains shut in because of its isolated location and unknown reserves.

At Farnham 102 million cubic feet of carbon dioxide were taken from one well and used in the manufacture of dry ice.

The only new gas well in the State in 1941 was completed in the Clay Basin field, with an initial daily capacity of 19.2 million cubic feet. Clay Basin has been operated under a unit agreement since January 1, 1940. It now has seven gas wells in the Dakota sand and two in the Frontier, which is not very productive. One Dakota well to each 600 acres is deemed to be productive.

Washington.—Unofficial reports indicate that natural-gas production in Washington ended in August or September 1941 with the shutting down of the depleted Rattlesnake Hills field and capping of the wells. Butane or propane gas probably was substituted for natural to meet obligations to customers in the Yakima Valley towns that have been served.

West Virginia.—Exploration and development continued to expand vigorously during 1941 as current and prospective demand for gas threatened to exceed the supply "in sight." Information is taken from a report by David B. Reger, consulting geologist, Morgantown, W. Va.

Reported new gas wells increased 19 percent to 558 in 1941. Total new daily capacity developed was 1,005 million cubic feet—including 56 million from 86 old wells deepened—almost 50 percent larger than the 1940 volume.

About 75 percent of the initial capacity added in 1941 was from the Oriskany sand, in which 166 gas wells were completed. Jackson supplanted Kanawha as the most active county, with 94 new Oriskany gas wells having a total initial daily capacity of 545 million cubic feet. About 14,800 additional acres were proved for Oriskany gas production in the Buttermilk-Sandyville gas pool. raising its total proved

territory to 16,000 acres. In Kanawha County, 68 Oriskany wells had 170.5 million cubic feet of initial daily capacity, averaging much smaller in size than the Jackson County wells. About 20,000 acres were added to the proved area of the Elk-Poca pool, making its total extent at the end of 1941 80,000 acres. The four Oriskany sand pools in the Charleston district now cover about 107,000 acres whose estimated original gas reserve in the Oriskany sand was approximately 600 billion cubic feet. Recovery thus far has been about 350 billion cubic feet, leaving an estimated supply of 250 billion available for consumption at the beginning of 1942.

Two Oriskany wells were completed in the Union district, Putnam County, on the west edge of the Elk-Poca gas pool. A successful wildcat in Lewis County, Freeman's Creek district, was completed with rotary tools in the Oriskany at a reported total depth of 7,325 feet. The open-flow capacity was 474,000 cubic feet and closed pressure 2,300 pounds. Oriskany sand failures were drilled in Boone, Harrison, Lincoln, Monongalia, Roane, and Wood Counties. The White Clinton sand was tested unsuccessfully in Harrison County, Grand district, by a rotary-drilled well that went to the record depth of 10,018 feet without finding commercial quantities of gas. Two dry holes through the Clinton were drilled in Kanawha County and one in Wood County.

The Trace Fork gas pool in the Curry district, Putnam County, was the most actively developed shallow-sand area in 1941. In all, 38 gas wells were drilled with a total daily open-flow capacity of over 30 million cubic feet. The proved area of the field was enlarged from 10,000 to 15,000 acres during 1941, most production coming from Salt sand, Big Lime, and Berea. Only a few wells have been drilled to the Devonian brown shale, which may eventually furnish much additional gas in this pool.

The total gas production in 1941 is estimated to have increased to 210 billion cubic feet.

Leading counties in gas-well completions were: Boone 32, Braxton 19, Cabell 16, Calhoun 46, Clay 20, Gilmer 37, Jackson 94, Kanawha 82, Lincoln 17, Putnam 46, Ritchie 33, Upshur 20, and Wayne 33.

Wyoming.—Five gas wells were drilled in old fields during 1941—one each at Bunker Hill, East Allen Lake, Elk Basin, Hiawatha, and Muskrat. The total daily open-flow capacity was 56.4 million cubic feet. Information is taken from a summary by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. The Elk Basin well was a field extension; the others were within the probable limits of fields previously established.

Three gas discoveries were made. A small well was drilled in sec. 10, T. 12 N., R. 101 W., at Canyon Creek, Sweetwater County, near an old and deeper dry hole. A wildcat well in sec. 31, T. 25 N., R. 88 W., on Sherard dome tested 5.8 million cubic feet from the Dakota and Lakota sands. It was continued unsuccessfully to the Tensleep formation in search of oil. A well in sec. 10, T. 29 N., R. 113 W., at Big Piney reported 15 million cubic feet of gas at a depth of 950 feet. Several good gas showings have been encountered in this area, but it is remote from existing gas lines or consuming centers.

The gross gas production increased 11 percent in 1941 to 43.4 billion

cubic feet, and metered or marketed production was 4 percent larger at 28.3 billion. Gas used in cycling or repressuring was 10.9 billion cubic feet in 1940 and 12.5 billion in 1941. The Salt Lake City gas system took 14.8 billion cubic feet of gas during 1941, an increase of 13 percent over 1940.

As a rule production was moderately higher in the principal fields, a notable exception being Big Medicine Bow, where a decline of over 50 percent was reported. Gas output of some larger fields in 1941 was as follows: Salt Creek 9,509 million cubic feet, Baxter Basin (entire field) 6,949 million, Lance Creek 7,294 million, Big Sand Draw 4,773 million, Muskrat 2,114 million, Little Buffalo Basin 1,737 million, Elk Basin 1,793 million, and Big Medicine Bow 584 million.

Salt Creek and Lance Creek continued to be the only fields where repressuring or pressure maintenance is being carried out on a large scale. The volume of gas injected in these fields totaled 6.4 and 4.8 billion cubic feet, respectively, in 1941. Small amounts also were returned to formations at Elk Basin, La Barge, Rock Creek, Wertz, and Grass Creek.

Gasoline plants processed 22,366 million cubic feet of gas in 1941, distributed by fields as follows, in millions of cubic feet: Salt Creek 9,466, Lance Creek 7,230, and Big Sand Draw 4,773, with small amounts at Rock Creek, Elk Basin, and Grass Creek.

CONSUMPTION

Consumption of natural gas in the United States in 1940 was the largest on record, increasing 7 percent over 1939 to 2,655 billion cubic feet. Domestic and commercial demand rose 13 percent—an unusual gain—owing to extremely cold weather in January and February 1940. The industrial load was higher than in 1939 by a modest 6 percent, as all types of demand expanded except that of fuel for electric power plants.

The average unit sales value of domestic and commercial gas has trended slightly downward since 1932. The number of meters has grown rapidly (42 percent), while the average consumption per meter has shown no definite trend, apparently responding chiefly to variations in weather conditions.

In the 8 years following 1932 the demand for natural gas more than doubled in each of 20 States, and total consumption increased 71 per-

[1] Includes natural gas piped from Canada.
[2] Small amount of gas consumed in Tennessee included with Virginia; separate figures not available.

cent. The gain of 460 billion cubic feet in Texas overshadowed that in other States from the standpoint of total volume; other important gains were in California, Louisiana, Illinois, Pennsylvania, and Kansas. Upon a percentage basis, the sharpest increases were in Michi-

gan, Minnesota, Maryland, Arizona, and Georgia; major gas lines have been laid to all those States since 1928 to open up new market areas.

Treated for natural gasoline.—Continued growth in recycling-plant operations in the Gulf Coast region was the major factor in an estimated 17-percent increase in volume of gas treated for gasoline extraction in the United States in 1941 to about 2,900 billion cubic feet. The continued decline in gasoline yield evidenced during 1941 is suggested by natural-gasoline production statistics, which indicate small reductions in the output of such important States as California and Oklahoma, where yields are above the national average, and pronounced gains in Texas and Louisiana, where yields are below the national average.

Final data indicate that in 1940 the volume of gas processed exceeded that in 1939 by 15 percent. The largest gains over 1939 were in Texas, Louisiana, West Virginia, Pennsylvania, and Illinois.

Natural gas treated at natural-gasoline plants in the United States, 1936–40, by States, in millions of cubic feet

Domestic and commercial.—Consumption of natural gas by domestic and commercial customers was notably lower during the early months of 1941 than in the corresponding 1940 period in all districts except California, because higher average temperatures prevailed. Unseasonably warm weather throughout the fall and early winter of 1941 in the Appalachian region curtailed the retail distribution of gas somewhat below normal expectancy. Therefore, domestic consumption is estimated to have increased less than 1 percent to 447 billion cubic feet in 1941 despite sharply increased national income and more domestic meters in use. Commercial use of gas increased 6 percent in 1941 to a new peak of about 143 billion cubic feet.

The average revenue received in 1941 per thousand cubic feet for gas sold is thought to have declined slightly to 70.8 cents from domestic consumers and 47.4 cents from commercial consumers. In 1940 the average value of domestic and commercial gas declined in all the larger consuming States except Pennsylvania, where a 6-percent increase was reported, probably reflecting a tight sellers' market for gas in the producing fields.

Domestic and commercial consumption of natural gas in the United States in 1940, by States [1]

[1] Includes natural gas used with manufactured gas. [2] Maryland includes District of Columbia and Virginia. [3] Utah includes North Dakota and Washington.

Field.—The reported field use of gas during 1941 is estimated to have decreased rather abruptly to 640 billion cubic feet from 712 billion in 1940, in consequence of a drop in consumption in Texas and Oklahoma. The 5-percent gain in 1940 field use of gas reported over 1939 can be ascribed almost entirely to Texas. The total for all other States was little changed, a decline in Oklahoma being balanced by small increases in a number of other States. Illinois had an exceptional increase from 2.2 billion cubic feet in 1939 to 7.8 billion in 1940, influenced by a boom in oil production.

The field-gas volumes in past years probably have experienced some inflation, particularly in Texas and Oklahoma. The questionnaire on which gas operations are currently reported defines more specifically the several types of gas utilization in the field, and it is anticipated that its effect will be to facilitate the construction of reports that will picture with increasing accuracy the actual functions gas performs.

Carbon-black manufacture.—Although carbon-black production increased about 4 percent in 1941, the quantity of gas used in its manufacture was slightly reduced to 365 billion cubic feet from 369 billion in 1940. The average yield of black per thousand cubic feet of gas burned rose to a new high of over 1.6 pounds. A trend to higher yields has been evident for several years, due to rapid growth in the production of furnace blacks, for which the yields are several times the average.

Petroleum refineries.—Consumption of natural gas as fuel at petroleum refineries increased 31 percent in 1940 over 1939 to 128 billion cubic feet, as this fuel supplied 17.1 percent of total heat requirements compared with 14.9 percent in 1939.[3]

Two principal trends encouraged the replacement of other fuels with natural gas in the Southwestern States. First, increasing quantities of refinery vapors formerly used as fuel are now utilized in production of "light-end" liquid petroleum products. Second, an upward trend in the market price of heavy fuel oil in 1940 and 1941 caused some diversion of this product from use as refinery fuel to sale on the open market. A further increase in use of natural gas as refinery fuel is estimated to have occurred in 1941, as it rose to 150 billion cubic feet, a new high.

Electric public-utility power plants.—Preliminary data indicate that 11 percent more natural gas was used at power plants in 1941 than in 1940—203,323 million cubic feet in 1941.

In 1940 such consumption dropped sharply in California as hydroelectric plants resumed normal operation after a severe drought. In New York, failing gas supplies virtually eliminated power plants as consumers. Consumption was lower also in the Illinois-Indiana-Ohio district and in Pennsylvania. Increases were general in areas of abundant gas supplies.

Portland-cement plants.—An unusually large increase (29 percent) in consumption of natural gas as fuel in portland-cement manufacture occurred in 1941 over 1940. The total consumed was 54,208 million cubic feet—a new high. Larger volumes of gas were used in all the chief consuming States, as cement production increased 26 percent over 1940.

[2] Maryland includes District of Columbia and Virginia

[3] Gas used in carbon-black manufacture included under "Miscellaneous" for United States total and under "Other industrial" for State total to avoid disclosing figures of individual operators.

[4] Utah includes North Dakota

Other industrial.—The demand for natural gas from miscellaneous industry is estimated to have increased 18 percent in 1941, rising to 760 billion cubic feet as the Federal Reserve Board index of industrial production rose from 136 for December 1940 to 163 for December 1941. Apparently this type of industrial use exceeded for the first time the volume of gas used in oil- and gas-field operations to become the most important class of natural-gas utilization from the standpoint of volume.

The demand from "Other industrial" had attained a new peak in 1940 at 642,594 million cubic feet, or 6 percent above 1939. The chief gains over 1939 were in such industrial States as Pennsylvania, Ohio, West Virginia, and Illinois. In sharp contrast was New York, where a shortage in gas supplies caused curtailment from 23.7 billion cubic feet in 1939 to 6.4 billion in 1940.

California, Pennsylvania, and Louisiana, in order, were the largest users in 1940 of "Other industrial" gas. A decade earlier, in 1930, the first three States in rank were Texas, Pennsylvania, and Louisiana. The greatest expansion in this type of gas market during the 10-year interval has been in California (from 27.0 to 85.4 billion cubic feet) and Illinois (from 6.5 to 52.3 billion). States added to the list of industrial-gas consumers since 1930 as a result of pipe-line construction include Arizona, Florida, Iowa, Minnesota, Virginia, and the District of Columbia.

Mixed gas.—The volume of natural gas used in mixtures with manufactured gas increased 12 percent in 1940 over 1939 to 65,102 million cubic feet, the largest total ever reported. Domestic and commercial consumption increased 10 and 11 percent, respectively, and industrial consumption reversed a 3-year decline by gaining 22 percent to reach 9,822 million cubic feet. The largest gains in industrial use were in Nebraska and Illinois.

The number of domestic and commercial meters in use increased 3 percent; sharp gains in Michigan, Nebraska, and Minnesota more than offset large losses in Missouri, New York, Ohio, Pennsylvania, and Virginia.

Consumption of natural gas used with manufactured gas in the United States in 1940, by States

State	Domestic		Commercial		Industrial (M cubic feet)	Total	
	Consumers	M cubic feet	Consumers	M cubic feet		M cubic feet	Value at points of consumption
District of Columbia	158,960	3,814,000	7,450	359,000	513,000	4,686,000	$3,262,000

Ohio	54,570	1,599,000	2,770	315,000	212,000	2,126,000	1,399,000
Pennsylvania	21,230	258,000	560	18,000	13,000	289,000	301,000
Virginia	600	24,000	250	12,000		36,000	37,000
Total: 1940	2,377,760	45,670,000	137,150	9,610,000	9,822,000	65,102,000	56,202,000
1939	2,297,010	41,395,000	132,990	8,679,000	8,039,000	58,113,000	53,952,000

The average value of the natural gas used with manufactured gas declined in 1940 to 86.3 cents per thousand cubic feet from 92.8 cents in 1939, influenced by the substantial gain in industrial consumption.

NEW MARKETS

Available reports indicate that natural-gas service was extended to over 50 communities in 12 States in 1941, affecting a population of about 300,000, of which more than half were in Illinois. A number of large military establishments and war industries were supplied with natural gas, particularly in the Southwest and in California, where this fuel is plentiful.

Larger municipalities reported as changing from manufactured gas to natural in 1941 included: Eureka (Calif.); Alton, Centralia, Mount Vernon, Belleville, and Granite City (Ill.); New Albany (Ind.); and Monroe (Mich.).

Rapid expansion of facilities for producing aluminum, magnesium, and other strategic materials will create new demands for natural gas.

INTERSTATE SHIPMENTS

The normal upward trend of interstate movement of natural gas, which was resumed in 1939, continued to a new peak of 738.8 billion cubic feet in 1940, a 7-percent gain over 1939. The vigorous growth in interstate shipment of gas began in 1928 when the pioneer construction of long-distance gas-transmission facilities was completed. Since 1927 the total increase has been 280 percent, as declines occurred only in the 1931–32 and 1938 periods of depressed business conditions.

Although moderate expansion of exports from gas-producing States has been the rule, Texas and Louisiana have been the principal sources of new gas for markets in other States. Their importance is indicated by the fact that 71 percent of the total increase in interstate movement in the 13-year period came from these two States.

In 1940, new peaks in gas exports were reported from Texas, Louisiana, Kansas, New Mexico, and Montana. The volume from West Virginia was the greatest in any year since 1920. Sharp declines in exports from Mississippi and New York occurred in 1940 because available gas reserves were being rapidly depleted. Demands for gas in Mississippi were met by increasing receipts from Louisiana. In New York many industrial consumers were compelled to change to other fuels because their normal demands could not be met from Pennsylvania sources, which also suffered from sharply reduced local supplies. Thus, shipments from Pennsylvania to New York were cut just when the need for them became great. The needs of Pennsylvania and Ohio consumers were met by substantially increasing receipts of gas from West Virginia, where important additions to available capacity have been made in recent years.

PIPE-LINE DEVELOPMENTS

Construction of natural-gas pipe lines continued at a high rate in 1941 for the second successive year, and 2,165 miles were completed. In addition, 460 miles were under construction at the end of 1941 and scheduled for early completion.

As in 1940, about one-third of the total new mileage was in loops added to existing major lines to increase their carrying capacity as market needs expand. In several instances, the 1941 expansion was a continuation of programs projected over a period of several years with the purpose of duplicating original trunk lines for their entire length.

The larger looping projects included 403 miles of 26-inch on the Texas Panhandle to Chicago line, of which about 350 miles were completed in 1941; 203 miles of 10- to 16-inch pipe on the line from southeast New Mexico fields to El Paso, Tex., and markets in Arizona; 55 miles of 18-inch added to the line from Monroe, La., to Memphis, Tenn.; 26 miles of 24-inch loop added to the Texas Panhandle to Minneapolis (Minn.) line; and 64 miles of 8- and 18-inch installed in the system that brings gas from Wyoming and vicinity to Salt Lake City, Utah.

About three-quarters of the new mileage was in the Southwestern States, with Texas most active. In all, 19 projects were reported in Texas, of which the following were the largest: 190 miles of 14- and 16-inch line from the West Ranch field to Beaumont to provide fuel for refineries; 27 miles of 12-inch from the Sewell field to Brad, Palo Pinto County; 19 miles of 12-inch to bring gas from the Grapeland cycling plant to the main line at Long Lake; 26 miles of 8-inch from West Beaumont to Port Arthur; 22 miles of 8-inch to bring gas from the Angleton field to Freeport; and 22 miles of 6- and 8-inch from Aldine to Houston.

Ten projects were reported for Louisiana, of which two were outstanding: The laying of 135 miles of 20-inch to bring gas from the Logansport field to a connection at Monroe with the main line serving Alabama and Georgia markets; and construction of a 216-mile line of 12-, 14-, and 16-inch originating in the Lirette field, La., and extending eastward to Mobile, Ala. A 25.6-mile section of this line is submerged under Lake Pontchartrain.

Oklahoma also had 10 new lines, most of which were small. The largest consisted of 55 miles of 16-inch pipe from the Cement field to connect with a major system near Oklahoma City. An 8-inch line was laid from Elgin to bring gas to Fort Sill, and 7.5 miles of 16-inch were laid from the Cement-field line to an airport near Oklahoma City.

Of five Kansas projects, one was of considerable size, in addition to the loops; it consisted of 146 miles of 8-inch running from Scott City, Kans., to Cambridge, Nebr.

No major new lines were reported in the Rocky Mountain States. The two largest were in Wyoming and consisted of 21 miles of 8-inch from the Garland field to the Elk Basin-Billings main line and 17 miles of 8-inch providing an outlet from the Powder Wash gas field to the Salt Lake City trunk line, connecting at Hiawatha.

Eight small lines were laid in the Illinois-Indiana area; the largest was 45 miles of 8-inch under construction from a trunk line at Peoria to Galesburg, Ill.

Thirty miles of 12-inch were laid in Ohio in Hocking, Fairfield, and Richland Counties, apparently terminating at Lucas.

Michigan reported six projects, among which were a 45-mile, 12-inch line under construction from Saginaw to Flint and a 39-mile, 12-inch line from Wise Station near Midland to McBain.

In West Virginia continued development of new supplies of gas near Charleston stimulated construction. Nine new lines were reported, the two largest being scheduled for completion early in 1942; these were 46 miles of 12-inch from Ripley to Waverly, Wood County, and 38 miles of 14- and 18-inch from New Era, W. Va., to Gravel Bank, Ohio. In Jackson County 38 miles of 6-, 8-, and 10-inch field lines were laid, and a 12-inch line was run from Goldtown to Ripley, a distance of 16 miles.

California had little activity, with only four small projects; the largest was about 19 miles of 12-inch connecting the Rio Vista field with the trunk line serving San Francisco at Woodbridge.

NATURAL GASOLINE

AND LIQUEFIED PETROLEUM GASES [1]

By F. S. Lott and A. T. Coumbe [2]

NATURAL GASOLINE

SUMMARY

To the natural-gasoline industry, 1941 was the most profitable of any recent year. The volume of production increased sharply (15 percent) to about 2,697 million gallons and set a new record for the second successive year. The total demand for natural gasoline outstripped production, gained 21 percent to 2,757 million gallons, and caused a draft of 60 million gallons on stocks.

Spot Mid-Continent prices, which began to recover late in 1940 from extremely low levels, averaged 2.4 cents per gallon in January 1941 and advanced steadily throughout the year to an average of 5.1 cents in December. Estimated yearly average values realized by producers are approximately 1 cent per gallon above spot prices. Such average values of 2.9 cents per gallon for 1940 and 4.7 cents for 1941 indicate that the gross value of natural gasoline distributed was 95 percent higher in 1941 than in 1940—a surprising improvement. Early in 1942, however, prices broke sharply as marketing facilities were restricted by transportation difficulties attributable to the war.

The proportion of natural gasoline blended in refinery gasoline returned in 1941 to a more nearly normal level (7.1 percent) from the 6.6 percent that had prevailed in 1939 and 1940.

Figures showing total exports for 1941 cannot be published; they are therefore combined with "losses" in this report.

The average yield of gasoline from natural gas probably continued the declining trend of recent years. Average vapor pressure, however, recovered from the low point of 1940 owing to increased requirements for the lighter products by refiners. This change may have been influenced in some degree by sharply higher demand for the ingredients from which aviation gasoline could be manufactured.

[1] Data for 1941 are preliminary; detailed statistics with final revisions will be released later.

PRICES AND MARKET CONDITIONS

After an all-time low of 1.5 cents per gallon in June 1940, the price of natural gasoline, as indicated by the market for the 26–70 grade in the Mid-Continent district, hardened gradually, then moved upward vigorously. The pressure of demand exceeded the peak production of 1941 and drove prices progressively higher from an

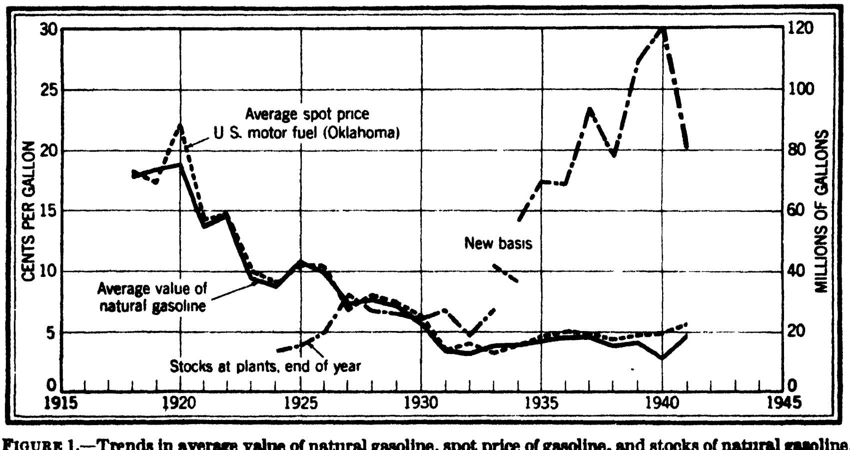

FIGURE 1.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918–41

average of 2.38 cents in January 1941 to the year's high of 5.13 cents in November and December; this proved to be the top of the rise, as a drastic price decline followed early in 1942.

In figure 1 the curve showing average values of natural gasoline is based upon estimates of the Bureau of Mines. The curve of average spot prices of United States motor fuel (Oklahoma) currently refers to 72–74 octane, after several adjustments from lower octane specifications. Past changes are described in detail on pages 985–987 of Minerals Yearbook, Review of 1940.

PRODUCTION

Trends in total output.—Except for temporary dislocations caused by unusual field developments, the trends of production of natural gasoline and crude oil have been roughly parallel for many years (see fig. 2). In 1941 the gain in natural-gasoline production over 1940 exceeded 15 percent, whereas that in crude-oil production was only 4 percent.

The chief cause of divergent trends in 1941 was rapid expansion of output by cycling plants whose operation is not directly related to rates of crude-oil yield. In Texas (and to a lesser extent in Louisiana) cycling-plant activity was reflected in sharply higher production of natural gasoline.

The rate of natural-gasoline output for the United States increased consistently during 1941 from a daily average of 6.7 million gallons in the first quarter to over 8.2 million gallons in the fourth quarter. Production of crude oil followed a similar, though more gradual, upward course.

[1] Subject to revision

California.—Natural-gasoline production fell 1 percent in 1941 to 580 million gallons and continued the decline that began in 1939, following the peak of gasoline yield from the great Kettleman Hills field. A modest gain in output of natural gasoline from the smaller fields included in the "Rest of State" section during 1941 could not offset the shrinkage in production from Kettleman Hills and Ventura Avenue.

Louisiana.—In 1941 production in Louisiana rose 61 percent to a new peak of 183 million gallons. Most of the increase in output was accredited to a new cycling plant in the Cotton Valley field in northwestern Louisiana, which began operating in July 1941. Its reported capacity exceeds 12 million gallons of liquid products per month, or enough to double the State's recent output of these products.

Oklahoma.—In 1941 natural-gasoline production continued the decline that began in 1938, the total being 381 million gallons compared with 399 million in 1940. Moderate declines occurred in all areas except Osage County, where an increase of 4 million gallons was reported.

Texas.—A 27-percent increase in Texas production to 1,183 million gallons in 1941 dwarfed the previous record output of 1940. Gains were reported in all districts except relatively unimportant North Texas and West Central Texas. The "Rest of State" and Gulf Coast areas, which include most cycling plants, showed conspicuous gains of 95 and 52 percent, respectively, in output over 1940.

As predicted in 1941 (in the preceding chapter of this series), the Gulf Coast area displaced the Panhandle as the leading producing district of Texas, despite a 13-percent increase in Panhandle production during 1941. Texas enlarged its proportion of the total natural-gasoline output of the United States to 44 percent in 1941 from 40 percent in 1940.

Natural gasoline produced and natural gas treated in the United States in 1940, by States [1]

State	Number of operators [2]	Number of plants operating	Natural gasoline produced: Thousands of gallons	Natural gasoline produced: Value at plants: Thousands of dollars	Natural gasoline produced: Value at plants: Average per gallon (cents)	Natural gas treated: Millions of cubic feet	Natural gas treated: Average yield per M cubic feet (gallons)

1939	[2] 260	684	2,169,300	90,050	4.2	2,150,000	1.01

[1] Complete figures for 1941 not yet available.
[2] A producer operating in more than 1 State is counted but once in arriving at total for United States.

Other States.—Except for insignificant declines in Colorado, Michigan, Montana, and Ohio, natural-gasoline production was larger in 1941 than in 1940 in each of the other producing States of this group. The largest gain (34 million gallons) occurred in Illinois, where rapid expansion of gasoline-plant operations continued for the third successive year in the wake of oil development. Material gains were reported also in West Virginia, Kansas, and New Mexico, where pronounced upward trends in natural-gasoline production have been evident for several years.

CONSUMPTION AND MOVEMENTS

Stimulated by conditions arising from the war situation abroad, the demand for natural gasoline in 1941 increased more than 20 percent to nearly 2,760 million gallons contrasted with 2,286 million in 1940. Production did not meet demand, prompting withdrawal of 60 million gallons from storage in 1941 and reversing the conditions of 1940, when 54 million gallons of natural gasoline were added to stocks.

Refinery utilization represented about 73 percent of total demand in 1941, as in 1940; "direct" sales absorbed 12 percent, and their relative importance increased from 10 percent in 1940. Exports and losses are grouped for 1941 to avoid disclosure of data regarding the former. They jointly amounted to 13 percent of total demand in 1941 and 15 percent in 1940.

Refinery utilization.—The proportion of natural gasoline used at refineries in motor fuel during 1941 increased to 7.1 percent after remaining at the comparatively low level of 6.6 percent in 1939 and 1940. A greater proportionate use of "natural" was reported generally in 1941, and the only notable decline was in the Oklahoma-Kansas-Missouri district (from 8.0 to 6.6 percent).

Percentage of natural gasoline in refinery gasoline in the United States, 1937–41, by districts

Year	East Coast	Appalachian	Indiana, Illinois, Kentucky	Oklahoma, Kansas, Missouri	Texas Inland	Texas Gulf Coast	Louisiana Gulf Coast	Arkansas and Louisiana Inland	Rocky Mountain	California	Total
1937	1.9	1.8	4.3	8.5	13.1	5.3	4.6	6.5	6.1	15.7	7.0
1938	1.6	1.4	4.7	8.8	15.5	4.3	2.2	6.8	5.8	17.6	7.2
1939	2.7	1.4	4.1	7.8	14.3	3.5	2.1	5.0	4.7	18.0	6.6
1940	2.0	1.6	4.5	8.0	16.6	4.4	1.7	3.3	4.5	15.7	6.6
1941 [1]	2.3	1.9	5.3	6.6	17.6	5.6	3.7	6.1	4.4	16.1	7.1

[1] Subject to revision

The wide variation among districts in the ratios of natural gasoline utilized in refinery gasoline (1.9 percent in the Appalachian region in 1941 to 17.6 in Texas Inland) suggests the great flexibility, from a technical standpoint, of this operation. Control of the ratio in a particular area is exercised chiefly by economic factors; geographic location and transportation costs probably dominate.

497779—43——75

"Direct" sales.—The pronounced upward trend in shipments of natural gasoline to jobbers, retailers, and refinery-owned bulk plants (which began in 1940 and continued through 1941) has been due almost entirely to Texas intrastate deliveries which in 1941 were five times those in 1939 when they comprised 22 percent of all "direct" shipments, as contrasted with 49 percent in 1941. Gains were reported in Louisiana and Arkansas deliveries. Cycling-plant operations play an important part in the Texas situation, for they produce much material that can be used as motor fuel with little or no additional processing.

Water-borne shipments.—All information regarding ocean movement of natural gasoline in 1941 must be withheld as a war measure to avoid giving possible aid to the enemy.

STOCKS

Stocks of natural gasoline in the United States declined from 240 million gallons at the end of 1940 to 180 million gallons on December 31, 1941, more than canceling the 54 million gallons added to stocks during 1940. Total stocks continued to accumulate in 1941 until a peak of 265 million gallons was reached in July; thereafter withdrawals were rapid until the end of the year.

About half of the net reduction in stocks took place at California refineries, where a downward trend persisted throughout the year. The other half was withdrawn from stocks at Texas plants and terminals during the latter 6 months of 1941. A 10-million-gallon increase in the relatively small stocks of natural gasoline at refineries outside of California was almost offset by an 8-million-gallon decline in plant and terminal stocks elsewhere than in Texas.

TECHNOLOGIC DEVELOPMENTS

Cycling plants.—Cycling operations in Texas increased at a slower rate in 1941 than in 1940. The daily average volume of gas processed in December 1941 was 1,413 million cubic feet—a 14-percent gain over December 1940. The yield of liquid products represented a daily rate of 37,458 barrels in December 1941 and 22,357 barrels in December 1940. The gain in cycling operations was somewhat greater than the foregoing data indicate because some repressuring-plant statistics were included in December 1940 totals and omitted in 1941.

During 1941 the number of cycling and repressuring plants reporting to the Railroad Commission of Texas increased from 32 to 45. In Louisiana the largest cycling plant in the world began operating in July 1941 in the Cotton Valley field, Webster Parish, and construction of a second large plant was started in December 1941 at South Jennings, Jefferson Davis Parish. Construction has begun on a cycling plant in the Katy field, Waller County, Tex., which may surpass the Cotton Valley plant in volume of output.

Yields.—Minor reductions in yield of natural gasoline were reported in 1940 in all the prominent producing States except Illinois, where a slightly higher yield was obtained. The chief gains in production were in such States as Texas and Louisiana, where yields are below the national average owing partly to the low yields from cycling operations. The influence of these developments is expressed in a decline in average natural-gasoline yield in the United States from 1.01 gallons per thousand cubic feet of gas processed in 1939 to 0.95 gallon in 1940. Similar trends in production were evident in 1941 and are thought to have caused a further slight decline in average yields in that year.

Production by processes.—The total number of gasoline plants in 1940 was unchanged from 1939; the only shift was the net gain of one absorption plant and the loss in West Virginia of one charcoal plant. The gain of 11 compression (including cycling) plants reported in Texas was offset by the dismantling of 11 plants in 5 other States. In recent years, major changes in gasoline-plant facilities have been (1) a rapid increase in the number of plants in Texas and (2) notable decreases in Oklahoma, Pennsylvania, West Virginia, and Kansas.

Natural-gasoline production by compression plants is growing rapidly because of the cycling operations in Texas, which contribute a major part of such output. Production by the absorption process continues to expand moderately in all important producing States except California and Oklahoma, where failing gas supplies have restricted the throughput in certain important fields.

Trends in vapor pressures.—The average vapor pressure of all natural-gasoline shipments in 1941 was 19.7 pounds, up from the 1940 average of 19.3 pounds. The rise was due entirely to deliveries to refineries, which increased in vapor pressure to 20.6 pounds from 20.2 in 1940, while the vapor pressure of shipments to jobbers remained unchanged at 13.8 pounds.

Technical improvements.—Mounting demand for suitable components for blending into 100-octane aviation gasoline caused rapid development of "superfractionation" equipment capable of isolating such lighter-end hydrocarbons as isobutane and isopentane in relatively pure form. This requires expensive apparatus designed to control critical processing conditions of temperature, flow, and fluid levels with an exactitude heretofore unrealized in commercial installations.

A general trend toward maximum recovery of the lighter hydrocarbons by gasoline plants was evident in 1941. These are useful as aviation-gasoline components, either direct or after conversion by isomerization and/or alkylation.

LIQUEFIED PETROLEUM GASES

The unusually active market for liquefied petroleum gases that prevailed throughout 1939 and 1940 continued with increased momentum into 1941, when sales of 462,852,000 gallons were reported, a 48-percent gain over the 1940 total of 313,456,000 gallons. The 1941 volume of deliveries to consumers would, it is believed, have been even greater had equipment for handling and using liquefied petroleum gases been freely available and diversions for consumption as raw material in the manufacture of high-octane gasoline and other products been less of a factor. The phenomenal growth in the demand for this fuel can be realized better when it is noted that the annual sales have quadrupled in 5 years; furthermore, the 1941 total for each of the several gases under review, except pentane, is above the combined total for all liquefied gases reported as recently as 1936.

Sales of liquefied petroleum gases in the United States, 1935–41, in thousands of gallons

Year	Butane	Propane	Butane-propane mixtures	Pentane	Total	
					Quantity	Percent of increase over preceding year
1935	34, 084	26, 814	13, 493	2, 464	76, 855	36.2
1936	40, 200	36, 502	27, 375	2, 575	106, 652	38.8

1939	71, 351	79, 323	69, 020	3, 886	223, 580	35.3
1940	77, 056	109, 216	123, 348	3, 836	313, 456	40.2
1941 [1]	112, 244	126, 969	219, 252	4, 387	462, 852	47.7

[1] Subject to revision.

All major demands for liquefied petroleum gases showed important gains in 1941 compared with 1940. Domestic requirements for cooking, water heating, and other household uses were 65 percent above the 1940 level compared with a 53-percent expansion in 1940 over 1939. A 41-percent increase in deliveries of liquefied petroleum gases for industrial fuel in 1941 compared with a 12-percent increment in 1940 largely reflects stepped-up defense activities. Gains in sales of liquefied petroleum gases to manufactured-gas companies and to chemical manufacturers—25 and 28 percent, respectively—are slightly below comparative percentage increases for the same industries in 1940. The outstanding spurt (81 percent) in the demand for liquefied petroleum gases to be used as internal-combustion-engine fuel in 1940 was not repeated in 1941—probably due partly to diversion of butane to other channels and to the question of future supply—and the volume of sales for the purpose exceeded the 1940 total by only 24 pe·cent.

Butane deliveries made up about one-quarter (24 percent) of the the total sales of liquefied petroleum gases in 1941, or the same proportionate share as in 1940. The propane total declined from 35 percent of all deliveries to 27 percent in 1941, and a corresponding gain (from 39 percent in 1940 to 47 percent in 1941) is found in the relative quantity of butane-propane mixtures reported. The decline in the proportionate volume of propane in the 1941 sales of liquefied petroleum gases is logical when it is considered that deliveries of propane gained only 16 percent compared with a 78-percent increase in the market for butane-propane mixtures. The bulk of propane requirements (77 percent in 1941) is reported for domestic use, where the unit of delivery is small and where consequently new customers, although numerous, add relatively little to the annual demand. On the other hand, the larger share of butane-propane mixtures is credited to the manufacturing and chemical industries and to motor-fuel demand, where requirements of individual consumers are proportionately large and fewer accounts can add materially to the total. It is believed, therefore, that the percentage of butane-propane mixtures in the annual sales probably will expand and the relative propane total will decline. The pentane item represents a very small part of the liquefied-petroleum-gas demand; furthermore, its proportionate share of the

total has dropped from about 2 percent in 1939 to less than 1 percent in 1941.

The marketed production of butane increased from 77,056,000 gallons in 1940 to 112,244,000 in 1941, or 46 percent, compared with a below-normal gain of 8 percent in 1940. Greatly increased demands for butane for domestic consumption (59 percent over 1940 requirements), industrial fuel (41 percent over 1940), and internal-combustion-engine fuel (67 percent higher than in 1940) were all important factors that caused the sharp rise in butane sales during 1941.

The demand for propane increased 16 percent—from 109,216,000 gallons in 1940 to 126,969,000 in 1941. The annual percentage gain for propane has declined noticeably for the third consecutive year from an increase of 47 percent in 1939 over 1938 to 38 percent in 1940 over 1939 and the still smaller increment in 1941 over 1940. Propane is used principally as a domestic fuel, a field in which the possibilities for great annual increases are less than for butane and butane-propane mixtures which go mostly to large-quantity consumers, such as industrial and chemical plants, and for motor-engine fuel. A 50-percent decline in demand for propane as an industrial fuel in 1941 (16,730,000 gallons in 1941 compared with 33,122,000 in 1940) reflects a reasonable shift to butane and butane-propane mixtures, fuels that are cheaper, that have higher B. t. u. content per gallon, and that can be handled at lower pressures. The unusual increase in quantity of propane reported under "All other uses" for the Pacific Coast area (2,329,000 gallons in 1941 and no deliveries in 1940) is said to be gas delivered to various Army camps for fuel purposes. It is known that a similar demand has developed in other areas, but the volume evidently has been reported under domestic use.

An unusually high gain in sales of butane-propane mixtures in 1940 was repeated in 1941, and deliveries increased from 123,348,000 gallons in 1940 to 219,252,000, or 78 percent. The quantity of butane-propane mixtures reported for domestic use more than doubled (increasing from 43,133,000 gallons in 1940 to 87,673,000 in 1941) and the total was not far below the total for propane, the liquefied petroleum gas generally associated with the domestic trade. Butane-propane mixtures sold for industrial fuel increased from 3,508,000 gallons in 1940 to 35,287,000 in 1941. Butane-propane mixtures evidently are replacing butane as industrial fuel, because greater quantities of the latter gas are now being diverted for raw material and blending agents in the making of various products. Chemical plants use important amounts of butane-propane mixtures in their processes, and this demand increased from 30,636,000 gallons in 1940 to 39,243,000 in 1941, or 28 percent. An unusually large volume of butane-propane mixtures was reported under "All other uses" in the Pacific Coast area; it is believed to cover deliveries to Army camps and defense housing projects, as is true of propane already mentioned.

The market for pentane increased 14 percent from 3,836,000 gallons in 1940 to 4,387,000 in 1941. Pentane is used chiefly by chemical-manufacturing establishments as raw material; however, the proportionate share for this purpose declined from 79 percent of the total in 1940 to 72 percent in 1941, whereas the demand for domestic use increased from 17 to 26 percent of total pentane deliveries.

[1] Subject to revision

In reviewing the relative quantities of the several liquefied petroleum gases delivered to satisfy the various uses, it should be noted that the proportion of butane in the domestic total was approximately 16 percent in both 1940 and 1941; the share of the domestic trade supplied by propane was 44 percent in 1941 compared with 51 percent in 1940 and a compensating gain was reported for butane-propane mixtures. This shift in kinds of liquefied gases sold for household fuel undoubtedly was due in part to the installation in the South Central States of numerous underground systems handling butane-propane mixtures for domestic use.

The manufactured-gas companies show proportionately more butane-propane mixtures and less butane in their purchases of liquefied petroleum gases in 1941 than in 1940. The butane share of such total requirements dropped from 53 percent in 1940 to 48 percent in 1941; most of this was compensated by the gain in butane-propane mixtures and the rest by propane deliveries.

Butane sold for industrial fuel was constant at about 47 percent of the total requirements for this use in both 1940 and 1941. Propane credited to industrial plants declined from 47 percent of the total in 1940 to 17 percent in 1941, but a corresponding gain (from 5 percent in 1940 to 36 percent in 1941) was reported for butane-propane mixtures in this particular use. Suppliers were believed to have been endeavoring to step up the volume of liquefied petroleum gases intended for industrial fuel by furnishing butane-propane mixtures, as they require less purification and consequently can be sold more cheaply. The demand for butane for other uses was another factor that caused more butane-propane mixtures to be used by industrial plants as fuel.

Liquefied petroleum gases credited to chemical plants for use as blending agents and raw material showed little change in their relative proportions in 1940 and 1941. Butane-propane mixtures comprised about 89 percent of the total in each year, and the rest was mainly pentane. Butane-propane mixtures are used widely as internal-combustion-engine fuel; however, the proportion of the total for mixtures dropped from 77 percent in 1940 to 69 percent in 1941, and most of the corresponding gain is found in the butane column and in a small increase for propane.

The following summary covering the distribution of liquefied petroleum gases by manufactured-gas companies in 1941 has been furnished through the courtesy of the American Gas Association.

At the end of 1941, liquefied petroleum gas was being delivered through mains to consumers in 175 communities in 31 States by 90 companies supplying 65,300 customers.

Butane-air gas with a heating value ranging from 520 to 1,300 B. t. u. per cubic foot was supplied to 142 communities in 30 States by 73 companies. A mixture of undiluted butane and propane gas with a heating value of 2,800 to 3,000 B. t. u. per cubic foot was supplied to 16 communities in Arizona, California, and Nevada by 7 companies. Undiluted propane gas with a heating value of 2,550 B. t. u. per cubic foot was supplied to 19 communities in Maryland, Minnesota, New Jersey, North Dakota, Virginia, and Wisconsin by 6 companies.

There has been a decided trend in recent years toward bulk handling of liquefied petroleum gases, because of the rapid growth in the proportion of deliveries to gas-manufacturing, industrial, and chemical plants and the motor-fuel trade, users that receive virtually all their requirements in tank cars or tank trucks. Bulk shipments of liquefied petroleum gases increased from 245,177,000 gallons in 1940 (78 percent of total sales) to 373,169,000 gallons in 1941 (approximately 81 percent of all deliveries), whereas cylinder shipments (limited largely to the domestic trade) were 68,279,000 gallons in 1940 and 89,683,000 in 1941. Ninety-six percent of all cylinder sales were credited to the domestic or "bottled-gas" market in 1941 compared with 97 percent in 1940.

The Pacific Coast marketing area (California, Oregon, Washington, Arizona, and Nevada) reported the sale of 102,885,000 gallons, or 22 percent of total national deliveries, in 1941 compared with 72,597,-000 in 1940, or 23 percent of all sales. Liquefied petroleum gases delivered in "All other areas" increased from 240,859,000 gallons in 1940—77 percent of total deliveries—to 359,967,000 in 1941—78 percent of the national demand.

CARBON BLACK

By G. R. Hopkins and H. Backus

SUMMARY OUTLINE

SUMMARY

The carbon-black industry experienced a profitable year in 1941, as new peaks were recorded for both production and sales. Because

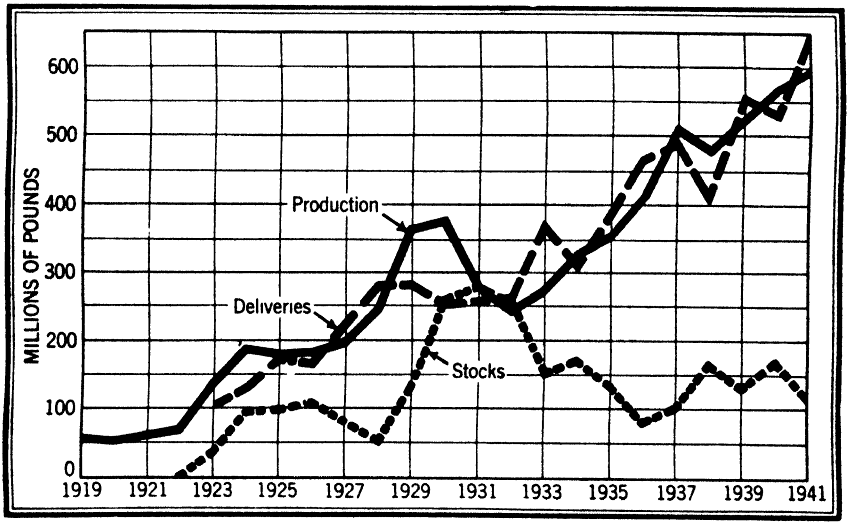

Figure 1.—Production, stocks, and deliveries of carbon black, 1919–41.

of the war, exports continued to decline but domestic sales advanced sharply. By the time the rubber shortage began to affect the market, other defense industries took up the slack, resulting in a 30-percent drop in producers' stocks between January 1 and December 31 (see fig. 1).

Prices were advanced on April 1 and July 1, then held firm until January 1, 1942, when there was another advance.

The use of carbon black is increasing in reducing glare on airport runways, in making black-out materials, and for military purposes; but in 1941, as in former years, the rubber industry was the largest user, taking almost 90 percent of domestic sales.

Salient statistics of carbon black produced from natural gas in the United States, 1937–41

PRODUCTION

By States.—In 1941 Texas produced 480,212,000 pounds of carbon black, or slightly more than in the former peak year of 1940. A decline of 9,000,000 pounds in production in the Panhandle was offset by the gain in output in the rest of the State. Texas supplied 81 percent of the total United States output in 1941 compared with 84 percent in 1940. Louisiana continued its upward trend and produced 78,050,000 pounds in 1941 compared with 55,610,000 pounds in 1940. Kansas and Oklahoma combined made an output of 35,803,000 pounds in 1941, compared with 33,287,000 in 1940.

Carbon black produced from natural gas in the United States in 1941, by States and by major producing districts

[1] In counting the total number of producers reporting, a producer operating in more than 1 State, district, or county is counted but once

By months.—War demands evidently influenced production, as the highest daily average output (obtained by prorating the Bureau's annual total upon the basis of monthly figures of the National Gas Products Association) was for December; the lowest were those for May and July.

Carbon black produced from natural gas in the United States in 1941, by months, in pounds

Month	National Gas Products Association[1]	Bureau of Mines[2]: Total	Bureau of Mines[2]: Daily average
January	41,842,851	50,136,000	1,627,000
February	37,934,158	45,684,000	1,632,000
March	42,258,613	50,911,000	1,642,000
April	41,324,480	49,783,000	1,659,000
May	41,385,780	49,842,000	1,608,000
June	40,076,944	48,298,000	1,610,000
July	41,371,402	49,842,000	1,608,000
August	41,589,962	50,139,000	1,617,000
September	40,216,651	48,476,000	1,616,000
October	40,521,599	48,832,000	1,575,000
November	41,193,670	49,604,000	1,653,000
December	43,313,845	52,218,000	1,684,000
	493,029,955	594,065,000	1,628,000

[1] Represents output of contact black.
[2] Monthly figures obtained by allocating the Bureau's annual total proportionately to the association's monthly data

Methods and yields.—Although the leading method of producing carbon black is still the channel process, the other processes—Lewis, roller, "special," and thermatomic—are gaining importance; they produced 18 percent of the total output in 1941 compared with 14 percent in 1940 and 12 percent in 1939. The principal gain was

made by the furnace or high-yield blacks; hence, the average yield rose to 1.63 pounds a thousand cubic feet of gas used compared with 1.54 pounds in 1940.

Number of plants.—There were 49 plants in operation in 1941 compared with 51 in 1940; 2 new plants were built, and 4 that produced in 1940 were not operated in 1941. Publication of information relative to location and capacity of plants has been suspended.

Producers.—The Reliance Carbon Co. was dissolved in 1941. No new names were added to the list of producers.

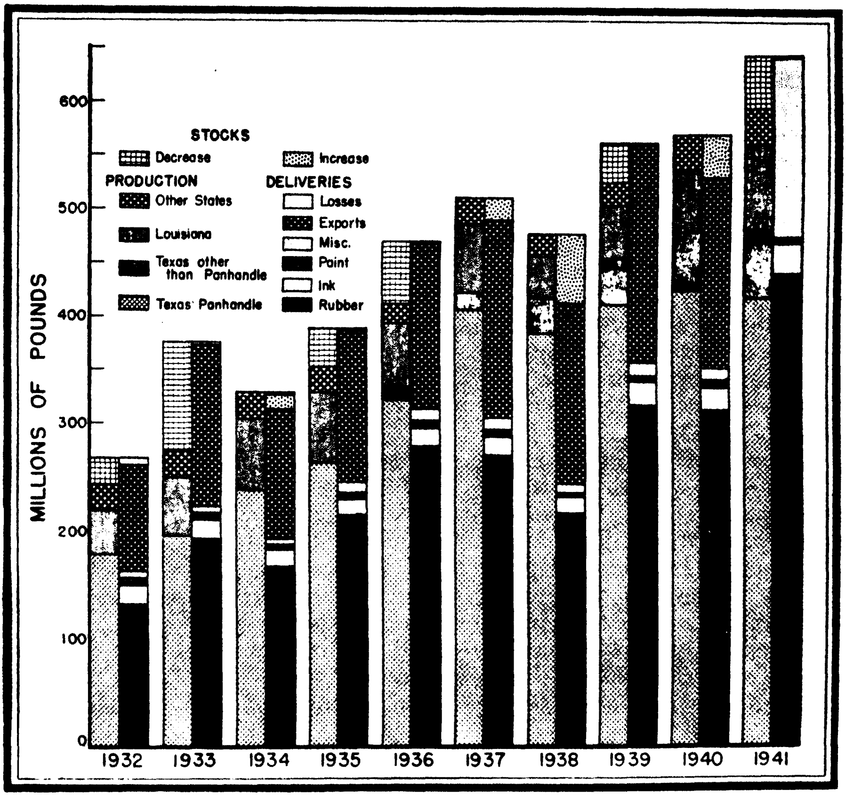

FIGURE 2.—Production and consumption of carbon black, 1932–41. Production in "Texas other than Panhandle" included in "Other States," 1932–35. Exports for 1941 included in "Miscellaneous."

DEMAND

Total deliveries.—Sales of carbon black, as reported by producers, were 644,744,000 pounds in 1941—22 percent above the 1940 figure of 529,774,000 pounds.

Domestic consumption.—Domestic sales increased in all major classes except those to paint companies. Because publication of exports for October, November, and December 1941 has been suspended, exports for the entire year 1941 have been combined in figure 2 with sales for miscellaneous purposes. It is not possible to compare relative sales of the major classes in 1941 with those in 1940.

497779—43——76

Reports from producers indicate that domestic sales in 1941 were divided as follows: Rubber companies, 439,502,000 pounds; ink companies, 28,198,000 pounds; paint companies, 5,840,000 pounds; miscellaneous purposes, including 3 months' exports, 58,469,000 pounds.

According to information supplied by the Bureau of Foreign and Domestic Commerce, the consumption of rubber, both at home and abroad, increased sharply in 1941.

Consumption of rubber in the United States reached a new peak, with substantial gains in all three types—crude, reclaimed, and synthetic. Statistics of the Rubber Manufacturers Association indicate that the percentage of decrease in stocks at the end of 1941 far outweighed the gain in number of tire casings produced, showing an increased demand made by the war on other branches of the rubber industry that use carbon black. The increased use of retread for tires is reflected in a sharp rise in the production of camelback. As this has a relatively high carbon-black content, it was probably also a factor in the 42-percent increase in the quantity of carbon black delivered to rubber companies during 1941.

A 17-percent increase in the quantity of carbon black delivered to ink companies is confirmed by information supplied by the Bureau of Foreign and Domestic Commerce, which shows new gains in newsprint available for consumption in 1941.

A 14-percent decrease in carbon black delivered to paint companies seems to indicate that its use in black-out paints did not affect the trade in 1941.

Exports and imports.[1]—Exports for the first 9 months of 1941 totaled 112,734,841 pounds, valued at $5,104,509; comparison with the corresponding period of 1940 shows a marked decline in shipments to foreign countries. The foregoing figures indicate an average value of 4.53 cents in 1941 compared with 4.38 cents in 1940. Publication of export figures for October, November, and December, and of the names of importing countries, has been suspended.

Imports of gas black for the first 9 months of 1941 were only 800 pounds, valued at $101. Imports of acetylene black (all from Canada) for the 9 months were 2,907,751 pounds, valued at $310,084.

Carbon black exported from the United States, 1940–41, by months

Month	1940		1941 (Jan.-Sept.)	
	Pounds	Value	Pounds	Value
January	20,109,979	$874,658	9,800,208	$454,687

1 Publication suspended.

1 Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

STOCKS

Favorable market conditions in 1941 were reflected in a 30-percent decrease in producers' stocks between January 1 and December 31. Stocks on hand at the end of the year were 118,847,000 pounds—the lowest figure since 1937, when 100,497,000 pounds were reported.

PRICES AND VALUES

The average value of carbon black at the plants rose from 2.90 cents a pound in 1940 to 3.26 cents in 1941.

The following table gives spot prices of representative grades of carbon black in 1941, as quoted by the Oil, Paint and Drug Reporter.

Quoted prices on various grades of carbon black in carlots in 1941, in cents a pound

HELIUM

By H. S. Kennedy and R. A. Cattell

SUMMARY OUTLINE

Introduction.—Planning and research by Bureau of Mines engineers, extending without interruption since the First World War, have resulted in a helium project that plays an important role in the present emergency. About 1925 the Bureau initiated (1) an accelerated program of research on properties of gases suitable for extraction of helium and (2) engineering studies of fields found in the course of the survey of helium-bearing natural gas that offered possibilities for economical extraction of helium. A successful helium project not only requires a supply of natural gas of suitable helium content but also a large proved reserve under a pressure of several hundred pounds per square inch (which can be protected against waste or rapid depletion through excessive withdrawals), an adequate and dependable outlet for the residue gas from the helium plant, and various other conditions essential to successful and economical extraction of helium.

The Cliffside field near Amarillo, Tex., was selected for a helium project and has proved to be the best source of helium-bearing natural gas found in 25 years of concentrated search. All gas rights were acquired in 50,000 acres of land covering the field, equipment using a new method for extraction of helium was designed, and the Amarillo Helium Plant (with a rated annual capacity of 24 million cubic feet of helium) was built in 1929.

Expanded program.—The importance of helium to the national defense program was recognized by the Congress in appropriating $175,000 in an act approved April 1, 1941, to be used in a survey of sources of helium for new helium plants and for additions to the existing facilities near Amarillo. With the funds made available, the Bureau is collecting and analyzing samples from various gas fields and studying geological and engineering features of fields that offer possibilities for production of helium. The primary purpose of this work is to acquire data that will aid in developing plans for increasing the output of helium to meet any helium requirements that may arise in the future. Moreover, at the end of the fiscal year 1941, the Congress appropriated $350,000 for another unit at the two-unit Amarillo plant and for drilling additional wells, thereby increasing the rated annual capacity of that plant to 36 million cubic feet. The new unit and other facilities being constructed near Amarillo will be ready for operation at the beginning of the fiscal year 1943.

The plans of the Army and Navy have progressed to such a point that the expanded facilities at the Amarillo plant will not supply enough helium for the war program. Therefore, the Congress made an additional $1,250,000 available to the Bureau of Mines for new helium-producing facilities. As a result of the survey and engineering studies, the Channing area in the southwestern part of the main Panhandle field (Moore, Potter, Oldham, and Hartley Counties, Tex.), which produces gas with an average helium content of about 1 percent, was selected as a source of helium-bearing natural gas. A site at Exell, Tex., has been selected for a new helium plant, to be constructed with a rated annual capacity of 24 million cubic feet of helium. A contract permitting the Bureau to process the gas from this area for helium extraction and contracts for the design and construction of a new plant have been executed.

Protection of plant and gas field.—Helium is used to inflate aircraft that patrol the coasts. The Amarillo plant is the only operating helium plant in the world, and the Cliffside gas field is therefore an essential war area as the source of helium-bearing natural gas. The military authorities and the Federal Bureau of Investigation have cooperated with the Bureau of Mines in studying means of protecting the plant, pipe line, and gas wells, and their recommendations for guarding the properties against sabotage have been put into effect.

Operation of Amarillo plant.—During the fiscal year ended June 30, 1941, the Bureau of Mines Amarillo Helium Plant operated at a rate higher than in any previous year and produced 16,173,430 cubic feet of helium; the cumulative output from April 1929 to June 30, 1941, was 116,165,430 cubic feet. During the first half of the fiscal year ended June 30, 1942, 15,721,950 cubic feet of additional helium were produced, raising the plant's total output from April 1929 to December 31, 1941, to 131,887,380 cubic feet. This quantity of helium, added to the 49 million cubic feet produced at the Fort Worth plant before the Amarillo plant was built, raises the total production in Government plants to approximately 180 million cubic feet at the end of the calendar year 1941.

Residue natural gas from the helium plant sold for use as fuel in the fiscal year 1941 totaled 845,728,000 cubic feet and brought a return of $38,057. The cumulative sales of residue gas for the 12-year operating period at the Amarillo plant (to June 30, 1941) totaled 5,997,936,000 cubic feet, for which $305,037 was received.

Cliffside gas field.—In the fiscal year 1941, 951,031,000 cubic feet of helium-bearing natural gas were produced by the Bureau of Mines from the Government's Cliffside gas field to supply the Amarillo plant; the cumulative output of natural gas from the field is 6,934,920,000 cubic feet.

The Bureau began a drilling program in the Cliffside field for a supply of gas in addition to that from the five wells drilled before 1941. Contracts were let for four wells, which were completed with daily open flows ranging from 11 to 22 million cubic feet of gas. Gathering lines were constructed to connect the wells to the main pipe line.

Government use of helium.—The Navy, which continued to purchase the largest volume of helium, received about 7 million cubic feet during the fiscal year 1941. Increased volumes of helium are used for inflating lighter-than-air craft to meet the expanding program of coast patrol. Helium is used for diverse fleet operations, including admix-

ture with oxygen to provide a breathing atmosphere that mitigates caisson disease (the "bends") in diving; the Bureau made pioneering experiments in this field in 1923.

The Weather Bureau consumed about 3,700,000 cubic feet of helium during the fiscal year 1941—over 40 percent more than in the fiscal year 1940. This increase was due to establishment of new meteorological stations and reflects the increased operations to supply the military services with weather data for extended war activities.

The Army employs helium principally for inflating barrage balloons, which are used in the rapidly expanding program of training soldiers to operate this type of war weapon for protecting military objectives from bombing. It is probable that barrage balloons flown above most objectives will be filled with hydrogen, but helium may be used where severe fire hazards will arise from hydrogen-filled balloons that may be shot down in flames. The extent to which helium will be employed in actual barrage-balloon operations will depend on future developments.

Sales of helium for medical, scientific, and commercial use.—Public sale of helium was authorized by the amendatory Helium Act approved September 1, 1937. To June 30, 1941, 124 contracts for a total of 2,761,095 cubic feet of helium had been approved. In the fiscal year 1941, 1,246,940 cubic feet of helium (7.7 percent of the production) were sold to non-Government users. About 600,000 cubic feet were employed for medical use, for an estimated 50,000 hours of treatment.

New uses for helium center around developments in metallurgy. Helium is being used as an inert atmosphere for welding magnesium-alloy wings for war planes, and this development has speeded their manufacture. Another use of helium in the national war program is to provide an inert atmosphere for welding defects in magnesium-alloy castings. It is reported that this use of helium has accelerated the production of magnesium castings.

Prices.—The estimated cost of producing helium for the fiscal year 1941, as approved by the Secretary of the Interior, was $13.75 a thousand cubic feet. In accordance with the law and regulations, this estimate was used as the basis for computing the deposits made by non-Government buyers of helium. Increased volume of output has a marked effect in reducing the unit cost of helium. Although production in the fiscal year 1941 was 71 percent more than that in 1940, the decrease in the unit cost was much less than it would have been in normal times because new obligations were incurred for protecting the helium properties against sabotage. The actual selling prices for the fiscal year 1941, as approved by the Secretary of the Interior, were $9.75 for helium for medical use, $10.24 for helium for scientific use, and $11.47 for helium for commercial use. The balances of the deposits under sales contracts, in excess of the total charges for helium and services applicable to the contracts, were refunded to the purchasers.

Government agencies were charged the record low price of $6.42 per thousand cubic feet, irrespective of the use made of the helium. This represents operating cost only, because under the law depreciation and depletion are not assessed against Government agencies.

The price at which helium can be sold is influenced by the volume of production and improvements in the process. Over a period of

years, the price of helium has shown a marked decrease. The trend in recent years is indicated by the following table:

Prices charged for 1,000 cubic feet of helium, 1938–41

[Exclusive of service charges]

	Fiscal year—			
	1938	1939	1940	1941
Helium requisitioned by Government agencies	$11.16	$11.47	$8.43	$6.42
Helium sold to non-Government purchasers.				
Medical use	13.471	12.80	11.17	9.75
Scientific use	13.471	13.44	11.73	10.24
Commercial use	15.088	15 05	13.14	11.47

Outlook and plans.—As most of the world is at war, the War and Navy Departments and the Weather Bureau have been obliged continually to expand their war plans involving the use of helium. The production in the fiscal year 1942 was nearly double that in the fiscal year 1941. The anticipated demand in the fiscal year 1943 will require the full rated annual capacity of 36 million cubic feet of helium from the three units at the Amarillo plant (including the new third unit) and large quantities from the new plant being constructed at Exell, Tex. The usefulness of the airship patrol in locating enemy submarines off the coasts has accelerated the program for constructing additional lighter-than-air craft, which, in turn, has increased the demand for helium. An increase in the annual capacity of the new plant at Exell, Tex., from the 24 million cubic feet originally contemplated to 60 million cubic feet is being considered.

Work is continuing on the survey of helium-bearing natural gas and the geological and engineering study of fields that give promise as sources of helium. This work will enable the Bureau of Mines to select areas for establishing new helium plants whenever they are needed to meet the requirements of war.

ASPHALT AND RELATED BITUMENS

By A. H. Redfield [1]

SUMMARY OUTLINE

SUMMARY

Refinery sales of petroleum asphalt (exclusive of road oil) to domestic consumers in the United States were 26 percent larger in tonnage in 1941 than in 1940, and, because of higher prices, they were 34 percent greater in total value. The average sales value per short ton increased 6 percent. To meet the augmented domestic demand, petroleum refineries enlarged their output 23 percent from 1940 to 1941 and decreased their stocks 1.6 percent. The increased domestic demand in 1941 was partly met by imports,which were 18 percent higher in the first 9 months of the year than in the corresponding months of 1940. At the same time, foreign demand was 22 percent less in the first three quarters of 1941 than in the corresponding period of 1940.

The tonnage of bituminous rock sold had an even greater proportional increase—43 percent—than did the total tonnage of solid and liquid petroleum asphalt sold for paving purposes—23 percent. The comparatively low valued products of Texas, Oklahoma, and Alabama accounted for the greater increases in sales of bituminous rock; consequently, the total value of bituminous rock sold increased only 19 percent, and the average value per short ton sold decreased 17 percent.

In spite of a slight decline in exports of natural unmanufactured asphalt (mostly gilsonite), sales of gilsonite increased 14 percent in quantity from 1940 to 1941. As the unit value of the gilsonite sold declined 3 percent, the total sales value increased only 10.5 percent.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—Bituminous rock shared the generally increased demand for asphaltic substances in 1941. Sales of rock asphalt by producers in the United States increased 43 percent in quantity—from 458,665 short tons in 1940 to 654,692 tons in 1941—and 19 percent in total value—from $1,949,166 to $2,312,227. Prices were lower than in 1940, and the average sales value at the mine decreased from $4.25 per ton to $3.53.

Operators in Texas and Oklahoma increased their sales from 282,250 tons valued at $833,248 to 446,432 tons valued at $1,197,319, but smaller sales in California more than offset an increase in Missouri.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

East of the Mississippi River, producers in Kentucky and Alabama enlarged their sales from 150,312 tons valued at $1,031,646 to 193,887 tons valued at $1,047,529.

Gilsonite and wurtzilite.—Greater demand in the domestic market boosted producers' sales of gilsonite in Utah from 31,930 short tons valued at $770,711 in 1940 to 36,407 tons valued at $851,623 in 1941. The average sales price per ton at the mine or railhead decreased from $24.14 to $23.39.

Sales of wurtzilite from Utah decreased from 70 tons valued at $5,460 in 1940 to 69 tons valued at $5,343 in 1941.

Sulfonated bitumen.—In 1941, as in 1940, a small quantity of natural sulfonated bitumen was produced in Box Elder County, Utah, near Ogden.

Exports.—Exports of natural unmanufactured asphalt were 8,223 short tons valued at $266,404 in the first 9 months of 1941, compared with 8,382 tons valued at $362,836 in the corresponding months of 1940. No data to indicate the destination of these exports in 1941 are available for publication.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Petroleum refineries in the United States produced 23 percent more asphalt in 1941 than in 1940. The Rocky Mountain district was the only exception to the general increase. The greatest gains in tonnage were made in the northeastern quarter of the United States and the Mid-Continent area; California and Gulf Coast refineries showed smaller increases.

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of asphalt (exclusive of road oil) at petroleum refineries in the United States in 1941, by districts, in short tons

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, losses, and exports	Sales to domestic consumers
			Dec. 31, 1940	Dec. 31, 1941		
East Coast	2,138,000	148,600	137,000	120,000	137,800	2,165,800

Arkansas and Louisiana Inland	227,986	1,561,379	315,116	2,210,082
Total Louisiana-Arkansas	537,632	4,390,863	679,001	5,706,283
Rocky Mountain	133,940	946,789	161,200	1,492,574
California	653,093	3,540,782	795,158	5,842,416
Total United States	4,942,289	45,191,051	6,228,723	60,513,143

Stocks.—Throughout the Nation, stocks of petroleum asphalt at refineries decreased 10,000 short tons from December 31, 1940, to December 31, 1941, principally in Louisiana and Arkansas, the East Coast district, and California. On the other hand, refinery stocks increased in Oklahoma, Kansas, and Missouri; in the Rocky Mountain district; and in Texas.

Sales.—Sales of petroleum asphalt by refineries to domestic consumers in the United States increased 26 percent in quantity and 34 percent in total value from 1940 to 1941; the average value at the refinery increased from $9.14 to $9.72.

Of the total petroleum asphalt sold to domestic consumers, 25 percent was manufactured from foreign petroleum (imported chiefly from Venezuela and Mexico), the same percentage as in 1940. Although runs of foreign crude oil to stills increased 22 percent—from 41,798,000 barrels in 1940 to 50,946,000 barrels in 1941—sales of petroleum asphalt from this source increased 27 percent in tonnage during the same period; apparently, more foreign crude oil was run to asphalt in 1940 than in 1941. East Coast refineries sold 91 percent of the total asphalt made from foreign crude in 1940 and 97 percent in 1941.

Highway and street construction and airport-runway surfacing used (in the form of paving asphalt, paving flux, cut-back asphalts, and asphalt emulsions) 64 percent of the total asphalt sold to domestic consumers by petroleum refineries in 1941, compared with 66 percent in 1940. Such statistics as are available indicate a sharp increase in the construction of paved highways over 1940. Not only was more mileage of high-type roadway laid down by the States, but the Federal Government contributed generously to the enlarged demand for paving grades of asphalt in 1941 by its program of constructing paved streets for camps and cantonments and runways for airports.

Domestic sales of paving asphalt of less than 200 penetration increased from 1,277,961 short tons in 1940 to 1,764,221 tons in 1941, or 38 percent. The gains were general but were greatest in the three

northeastern districts, in Louisiana and Arkansas, and in California. It is noteworthy that the three northeastern refining districts, which produced 58 percent of the paving asphalt sold in the United States in 1941, laid 62 percent of the high-type surface constructed in that year, according to Engineering News-Record.

Asphalt and asphaltic material (exclusive of road oil) sold at petroleum refineries to domestic consumers in the United States in 1941, by varieties

[Value f. o. b. refinery]

Rocky Mountain	8,165	26,773
California	195,548	276,059
Total United States	1,277,961	1,764,221

Increased construction of lighter-type asphaltic highways is indicated by greater sales of cut-back asphalts than in 1940. Total sales of rapid-curing and medium-curing cut-backs increased 10 percent in quantity—from 1,722,475 to 1,903,132 tons. The greatest gains were in the East Coast district, the Oklahoma-Kansas-Missouri district, the Louisiana-Arkansas district, Texas, and the Rocky Mountain district. Against these gains were a sharp decline in the Indiana-Illinois-Kentucky-etc. district and smaller declines in California and the Appalachian district. Most of the gain in sales of cut-back asphalts was in the medium-curing type, and the greatest increases in that type were in the East Coast and Oklahoma-Kansas-Missouri districts.

Cut-back asphalts sold at petroleum refineries in the United States, 1940–41, by districts, in short tons

District	1940	1941
East Coast	449,368	576,779
Appalachian	50,940	46,526

Total Texas	122,428	141,058
Louisiana-Arkansas:		
Louisiana Gulf Coast	125,738	143,544
Arkansas and Louisiana Inland	45,835	48,507
Total Louisiana-Arkansas	171,573	192,051
Rocky Mountain	100,634	114,739
California	234,320	228,427
Total United States	1,722,475	1,903,132

Petroleum refineries sold 85,570 short tons (20,162,003 gallons) of emulsified asphalts and fluxes valued at $887,202 in 1940 and 129,006 tons (30,396,265 gallons) valued at $1,576,840 in 1941; in addition, 45,924,626 gallons valued at $3,385,468 in 1940 and 76,830,549 gallons valued at $6,919,102 in 1941 were sold by major industrial companies that purchased asphalt from petroleum refineries. Accordingly, total known sales of emulsified asphalts and fluxes increased 62 percent in quantity—from 66,086,629 to 107,226,814 gallons—and 99 percent in value—from $4,272,670 to $8,495,942.

Roofing manufacture made the second-largest demand for asphalt, absorbing 25 percent of the sales to domestic consumers in 1940 and 27 percent in 1941. Although shipments of prepared roofing and asphalt siding reported to the Bureau of the Census increased 29 percent—from 34,222,039 squares in 1940 to 44,112,699 squares in 1941—domestic sales of roofing asphalt and roofing flux combined increased 37 percent—from 1,218,695 to 1,671,696 tons. Some roofing and asphalt siding, however, is made by petroleum refiners who do not report their consumption of asphalt for roofing manufacture among their sales. The increase in sales of roofing asphalt and flux was general. The principal gain was in the northeastern quarter of the United States—notably in the East Coast and Indiana-Illinois-Kentucky-etc. districts. Substantial gains occurred also in the Oklahoma-

Kansas-Missouri district, in Inland Texas, in Inland Louisiana and Arkansas, and in California.

FOREIGN TRADE

Imports.—Imports of natural asphalt and bitumen into the United States during the first 9 months of 1941 totaled 8,866 short tons valued at $118,061 compared with 10,313 tons valued at $120,163 in the corresponding months of 1940. For the same periods, imports of lake asphalt from Trinidad declined from 7,949 tons valued at $81,353 in 1940 to 6,017 tons valued at $66,323 in 1941. On the other hand, imports of grahamite from Cuba increased from 1,914 tons valued at $33,907 in the first three-quarters of 1940 to 2,774 tons valued at $47,813 in the corresponding period of 1941.

Imports of solid petroleum asphalt decreased from 30,230 short tons valued at $168,006 in the first 9 months of 1940 to 18,987 tons valued at $64,806 in the corresponding months of 1941. From January to September 1940, Netherlands West Indies supplied 28,517 tons valued at $115,207 and Mexico 1,632 tons valued at $51,350.

In addition, Mexico supplied 152,320 barrels (27,695 short tons) of liquid petroleum asphalt, including cut-backs and road oil, valued at $127,949 during the first three quarters of 1940 and 291,531 barrels (53,006 tons) valued at $352,220 during the corresponding quarters of 1941.

Exports.—Exports of petroleum asphalt decreased from 209,581 short tons valued at $3,194,981 in the first 9 months of 1940 to 163,461 tons valued at $2,500,001 in the corresponding months of 1941. No data to indicate the destination of exports during the first three quarters of 1941 are available for publication.

DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States increased from 5,279,056 short tons in 1940 to 6,722,832 tons in 1941, according to freight-

commodity statistics compiled by the Interstate Commerce Commission. The increase was general; but the largest gains were in terminations by railroads of the Eastern district, operating east of the Mississippi and Illinois Rivers and north of the Ohio and Potomac Rivers. West of the Mississippi River the gains were greatest in the Central Western region, bounded by Chicago, Peoria, St. Louis, Kansas City, El Paso, the boundary with Mexico, and Portland, Oreg.

Asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States, 1940–41, by districts and regions, in short tons

District and region	1940	1941
Eastern district:		
New England region	205,093	301,764
Great Lakes region	1,088,482	1,482,260
Central Eastern region	1,360,132	1,827,661
Total Eastern district	2,653,707	3,611,685
Southern district:		
Pocahontas region	166,738	199,807

Central Western region	924,705	1,109,322
Southwestern region	307,463	354,000
Total Western district	1,770,196	2,049,065
Total United States	5,279,056	6,722,832

ROAD OIL

Refinery sales of road oil to domestic consumers increased 5 percent in quantity—from 8,444,000 barrels in 1940 to 8,831,000 barrels in 1941. Higher prices brought an increase of 30 percent in value—from $9,457,000 to $12,252,000.

Of the road oil sold in the United States to domestic consumers in 1941, only 365,908 barrels valued at $647,546 were made from foreign petroleum, imported chiefly from Venezuela and Mexico. Of the road oil made from foreign crude oil, nearly all was sold by refineries of the East Coast district.

CEMENT

By Oliver Bowles and E. V. Balser

SUMMARY OUTLINE

GENERAL CONDITIONS

The portland-cement industry of the United States experienced unusual activity in 1941. Production increased from 130,216,511 barrels (376 pounds each) in 1940 to 164,030,559 barrels in 1941—a 26-percent gain—according to final annual returns submitted by cement companies to the Bureau of Mines. Shipments increased from 130,349,786 barrels valued at $190,078,068 in 1940 to 167,439,237 barrels valued at $246,621,914 in 1941—a gain of 28 percent in quantity and 30 percent in value. The preliminary figures on production for 1941 (published by the Bureau of Mines in January 1942) were 0.02 percent less and shipments 0.04 percent more than the final figures.

The Federal Reserve Board annual index (1935–39=100) for cement production was 154 in 1941 compared with 122 in 1940; for the durable-goods industries it was 193 in 1941 and 135 in 1940. Indexes for total new construction were, respectively, 208 and 137.

In 1941, 155 plants manufactured and shipped portland cement compared with 152 plants in 1940.

The average factory value was $1.47 a barrel in 1941 compared with $1.46 in 1940.

Shipments included 6,123,224 barrels of high-early-strength portland cement valued at $11,443,792 (an average of $1.87 a barrel) in 1941 compared with 4,401,449 barrels (revised figure) valued at $8,243,315 (revised figure) (an average of $1.87 a barrel) in 1940.

The quantity of natural, masonry (natural), and puzzolan cements produced increased 13 percent and shipments 16 percent compared with 1940. The value of shipments of these varieties gained 17 percent.

The preceding figures cover briefly the condition of the cement industry in 1941, and the following tables present its outstanding features during recent years.

Salient statistics of the cement industry in the United States, 1938–41

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

Portland cement occupies a dominant position in modern civilization. Although invented only 118 years ago, it is now regarded as indispensable in highways, sidewalks, bridges, and dams; in the construction of virtually all large buildings; and in airport runways, dry docks, harbors, and a multitude of other major and minor projects. Both farmers and city dwellers use it in innumerable ways.

Cement is immeasurably important in facilitating the far-reaching program of military expansion that is steadily climbing toward a

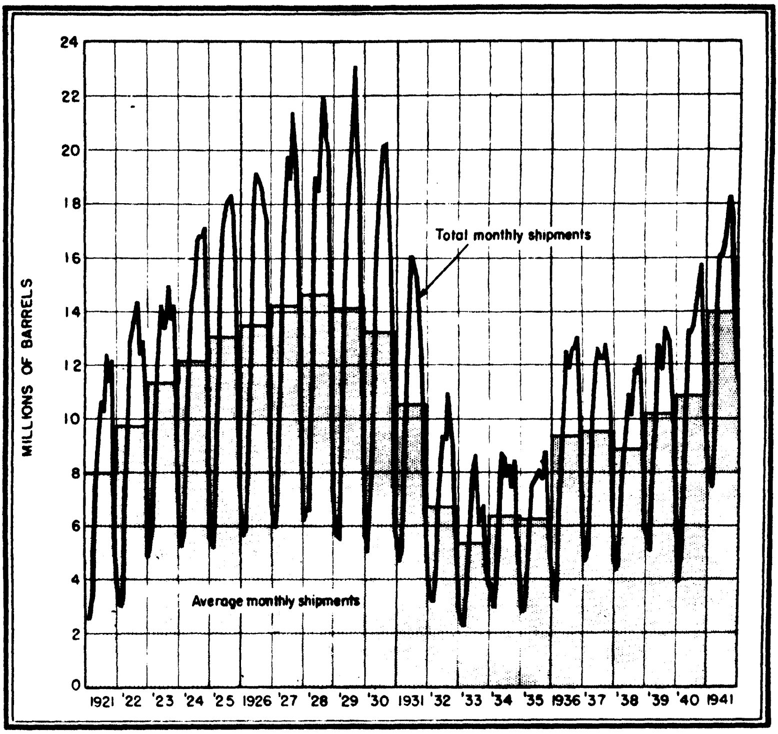

FIGURE 1.—Total monthly and average monthly shipments of portland cement in the United States, 1921-41.

climax. Many military projects require enormous quantities of cement, and even the hastily built temporary types of war construction ordinarily must have cement foundations if safety and stability are to be assured. The increase in shipments, amounting to 28 percent in 1941 compared with 1940, was due largely to the growing requirements of military establishments under construction in numerous localities throughout the United States.

Cement shipments fluctuate greatly, according to the season. Figure 1 shows the volume of portland cement shipped each month compared with the average monthly shipments for each year. The chart shows that the fluctuations are lessening gradually, a condition due partly to improved adaptability of cements to cold-weather use

and partly to a growing movement toward winter construction. Because of the strong demands for military uses, the recession in shipments during the latter months of 1941 was less pronounced than in the pattern of previous years.

Common, general-purpose portland cement is the principal product, but large quantities of special types are also marketed. They have been developed during recent years to satisfy new conditions that have arisen in construction. Thus high-early-strength cement is used where time-saving is important, low- or moderate-heat-of-hydration cements have become a necessity in the construction of monolithic dams, and special oil-well cements have made it possible to solve difficult problems in the petroleum industry. Statistics for all varieties are given in the general portland-cement tables, and the special varieties are discussed in more detail, with statistics wherever available, in a later section of this report. The special portland cements are to be distinguished from certain other types, such as natural and slag-lime cements, which are not true portland cements and are covered in a separate section of this chapter.

The principal statistics of portland cement appear in the following tables. In the first, which relates to production, shipments, and stocks by States and districts, the term "active plant" is applied to a mill or group of mills situated at one place and operated by one company. If a company has establishments at different places, its mill or group of mills at each place is counted as one plant. The districts are groups of States related geographically and commercially.

The tables giving data by months, compiled from monthly reports of the producers, include figures on clinker or unground cement produced and in reserve at the mills awaiting manufacture into finished cement. Although the figures may differ slightly from those based upon annual reports of the producers, they accurately reflect seasonal fluctuations in the industry.

	Clinker	4,575,000	do	4,192,000	do	6,276,000

[1] Includes Puerto Rico (1939 was first year in production).
[2] Revised figure.

DOMESTIC CONSUMPTION

Apparent consumption (shipments plus imports minus exports) for the entire United States for a series of years is indicated in the salient statistics presented as the first table in this chapter. The only available gage of consumption by States is the record of shipments into States by manufacturers; it is therefore merely approximate. Cement shipped to destinations within a State in which it is manufactured is, of course, added to that shipped from other States. Shipments into a State during any year may not equal the consumption during that year but over a series of years should afford a fair index of consumption. The following table shows shipments into States in 1940 and 1941 and per capita consumption in each State.

Shipments of domestic portland cement from mills into States and per capita, 1940–41, in barrels

State	1940		1941	
	Total	Per capita [1]	Total	Per capita [1]
Alabama	1,458,811	0.51	2,491,851	0.88
Arizona [2]	558,629	1.12	793,838	1.59
Arkansas	812,931	.42	1,146,712	.59
California	11,619,397	1.68	16,850,718	2.44
Colorado	1,028,753	.92	1,520,646	1.35
Connecticut [2]	1,893,733	1.11	2,379,471	1.39

Total shipped from cement plants	130,349,786		167,439,237	

[2] Non-cement-producing State.
[3] Includes shipments to Alaska, Hawaii, Puerto Rico, and foreign countries.

The per capita consumption indicated in the foregoing table falls short of the total apparent consumption by the quantity of imports, which affects to a limited extent certain States near the Canadian border and the seaboard.

The accompanying table of monthly shipments from portland-cement mills into States in 1941 is based upon monthly reports of producers. Although the totals may vary slightly from figures shown in tables based upon annual reports, they show seasonal fluctuations with fair accuracy.

Portland cement shipped from mills into States in 1941, by months, in barrels

[1] Includes shipments to Alaska, Hawaii, Puerto Rico, and foreign countries

LOCAL SUPPLIES

The following table compares the shipments from mills within a State or group of States with the estimated consumption (State receipts of mill shipments) and indicates the surplus or deficiency in the supply of cement locally available. Consumption in the States that do not produce cement is indicated in a preceding table showing shipments into each State.

The surplus cement shown in this table was distributed as follows: In 1940—to non-cement-producing States 13,703,729 barrels and to foreign countries, Alaska, Hawaii, and unspecified destinations 2,863,034 barrels; in 1941—to non-cement-producing States 16,880,678 barrels and to foreign countries, Alaska, Hawaii, and unspecified destinations 5,919,919 barrels.

Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1940–41, in barrels

TRANSPORTATION

The following table for 1939, 1940, and 1941, showing quantities of portland cement shipped from mills by truck, railroad, and boat, in bulk and in containers, is given because charges for transportation and delivery are important items in the cost of cement to consumers. Data for mode of shipping were lacking in 1939 for 5,681,405 barrels—about 5 percent of total shipments for the year.

The table presented herein is based upon the quantities of cement actually apportioned by the reporting companies; as it represents a very large proportion of the total quantity shipped, it may be assumed that the percentages thus obtained are approximately correct for the industry as a whole.

The earliest data obtained by the Bureau of Mines, those for 1928, show that 2.4 percent of total cement shipments was shipped in bulk

and 97.6 percent in containers. Shipments in bulk were reported in 1939 by 137 plants, representing 33 States; in 1940 by 144 plants, representing 32 States; and in 1941 by 150 plants, representing 35 States.

Shipments of portland cement from mills in the United States, 1939–41, in bulk and in containers, by types of carriers

[Unit of measure, barrels of 376 pounds]

Type of carrier	In bulk		In containers				Mode of shipping not stated	Total shipments	
			In bags		In other containers [1]	Total in containers			
			Paper	Cloth

[1] Includes steel drums and iron and wood barrels.
[2] Includes shipments for Puerto Rico.
[3] Includes cement used at mills by producers as follows: 1939, 132,238 barrels; 1940, 118,709 barrels; 1941, 196,765 barrels.
[4] Revised figures.
[5] Less than 0.05 percent.

PRICES

The average selling price of portland cement, f. o. b. factory (excluding the price of containers and cash discounts), as reported to the Bureau of Mines, is stated in the table of shipments by States and districts during 1940 and 1941. The average factory value in some States is higher than the average for ordinary structural cement because considerable quantities of certain special cements that command relatively high prices are included—for example, white portland cement manufactured in California, Pennsylvania, and Texas and high-early-strength portland cement produced in many States. The average selling price per barrel, f. o. b. factory, of white portland cement in 1941 was $3.99; in 1940 it was $3.89. The average price f. o. b. mill of high-early-strength portland cement was $1.87 a barrel in 1940 and 1941. The sales value of other hydraulic cements is given later in this chapter.

The following table shows the average factory value of portland cement from 1937 through 1941.

Average factory value per barrel in bulk of portland cement in the United States, 1937–41

1937	$1.48	1940 [1]	$1.46
1938	1.45	1941 [1]	1.47
1939 [1]	1.47		

[1] Includes Puerto Rico (1939 was first year in production).

LOCATION OF PLANTS

The accompanying map (fig. 2) shows the location of cement plants in the United States. Raw materials for manufacture of portland cement are so plentiful and widely distributed that other factors, such as markets and transportation facilities, are usually the principal elements that control selection of plant location. Most of the plants are contiguous to populous industrial centers. About four-fifths of all the portland-cement plants in the United States are in the Eastern and Middle Western States. Throughout the Great Plains and Rocky Mountain country they are more scattered. Concentrations of plants on the Pacific coast (California and Washington) are due partly to the requirements of growing industrialization areas and partly to the extensive demands of great reclamation projects. Only 12 States and the District of Columbia have no cement plants, and the greatest number in any one State (Pennsylvania) is 26; the Nevada plant was under construction in 1941.

CAPACITY OF PLANTS

At the end of 1941 the capacity of plants producing finished portland cement was 247,359,000 barrels a year, according to manufacturers' reports. This comprised 155 plants active and shipping in 1941 and 1 plant inactive in 1941 but producing or shipping from stock on hand within the 7 previous years.

No new plants were reported producing in 1941. The total output for 1941 was 66.3 percent of the indicated capacity at the close of the year, based upon producers' reports; the corresponding figure for 1940 was 51.2 percent.

Plant capacity in 1941, by commercial districts, is indicated in the following table, with similar data for 1940.

The second table shows a grouping of plants by size.

Portland-cement-manufacturing capacity of the United States, 1940–41, by commercial districts

District	Estimated capacity (barrels)		Percent of capacity utilized	
	1940	1941	1940	1941
Eastern Pennsylvania, New Jersey, and Maryland	48,718,000	45,274,000	51.3	68.5
New York and Maine	17,408,000	17,244,000	50.5	69.6
Ohio, western Pennsylvania, and West Virginia	27,526,000	26,574,000	48.6	57.0
Michigan	15,196,000	14,055,000	56.6	67.5
Wisconsin, Illinois, Indiana, and Kentucky	29,724,000	28,267,000	42.6	57.4
Virginia, Tennessee, Alabama, Georgia, Florida, and Louisiana	25,786,000	24,512,000	57.1	81.5
Eastern Missouri, Iowa, Minnesota, and South Dakota	22,871,000	22,475,000	45.1	52.8
Western Missouri, Nebraska, Kansas, Oklahoma, and Arkansas	17,113,000	16,598,000	44.4	59.7
Texas	12,240,000	12,352,000	60.3	78.4
Colorado, Montana, Utah, Wyoming, and Idaho	5,690,000	5,815,000	52.1	68.0
California	24,040,000	26,290,000	59.1	75.8
Oregon and Washington	7,447,000	7,440,000	57.3	58.9
Puerto Rico	386,000	463,000	100.0	99.9
	254,145,000	247,359,000	51.2	66.3

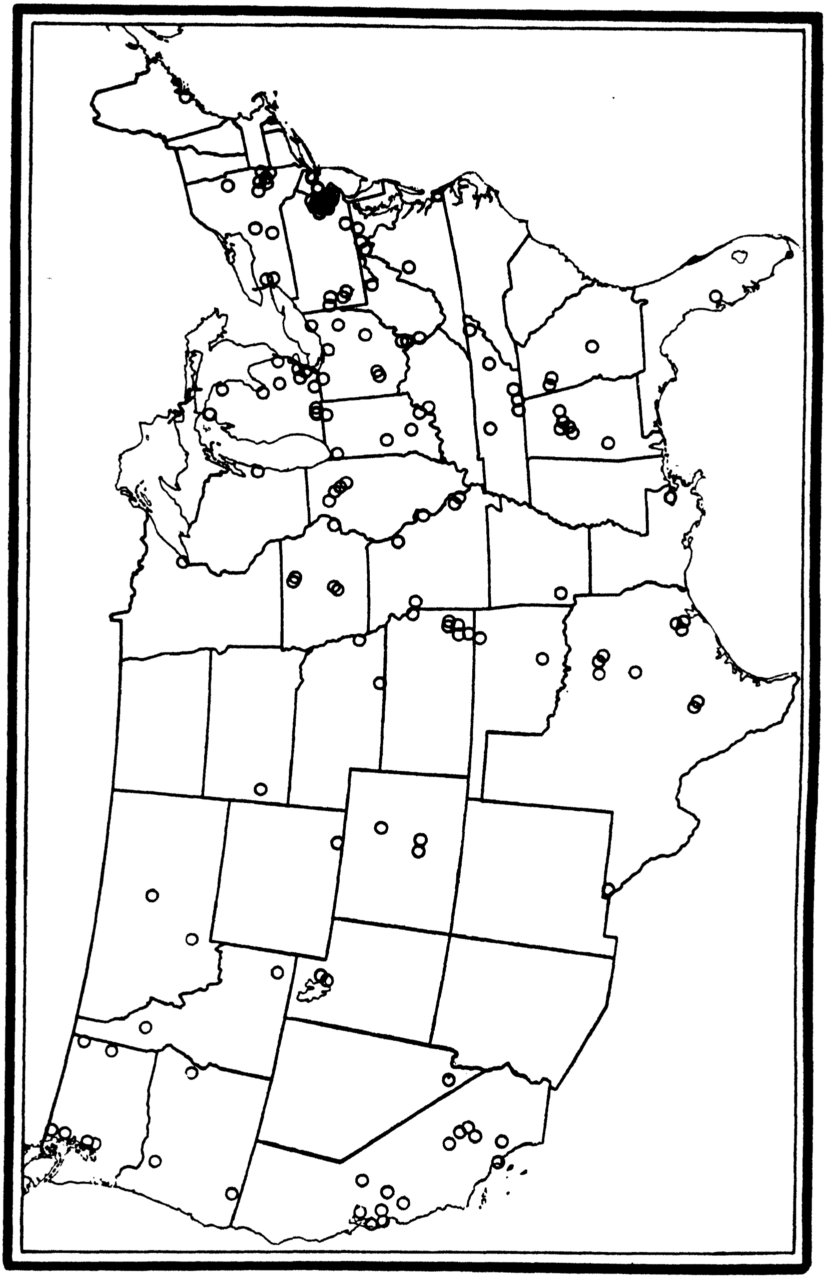

FIGURE 2.—Location of cement plants in the United States.

PRODUCTION ACCORDING TO RAW MATERIALS

In the accompanying table, production is classified according to the kinds of raw materials from which the cement is manufactured.

Type 1 includes cement produced from argillaceous limestone ("cement rock") or from a mixture of cement rock with pure limestone. This is the combination of materials used in all the cement plants of the Lehigh district of Pennsylvania and New Jersey, and a few plants in certain other States.

Type 2 includes cement made from a mixture of comparatively pure limestone with clay or shale. This mixture is employed at the majority of plants in the United States. In 1941 four plants reported the use of oystershells and clay; the output of these plants is included in type 2.

Type 3 includes cement manufactured from a mixture of marl and clay. This type of mixture has been used in certain plants in Michigan, Ohio, Indiana, New York, and Virginia.

Type 4 includes portland cement manufactured from a mixture of limestone and blast-furnace slag.

Production and percent of total output of portland cement in the United States, 1898–1914, 1926, 1929, 1933, 1935, and 1941, according to types of material used

Year	Type 1 Cement rock and pure limestone		Type 2. Limestone and clay or shale		Type 3. Marl and clay		Type 4. Blast-furnace slag and limestone	
	Barrels	Percent	Barrels	Percent	Barrels	Percent	Barrels	Percent
1898	2,764,694	74.9	365,408	9.9	562,092	15.2

1941	46,534,193	28.4	[1] 102,285,699	62.4	3,142,021	1.9	12,068,646	7.4

[1] Includes output of 2 plants using oystershells and clay in 1926; 3 plants in 1929, 1933, and 1935; and 4 plants in 1941

RAW MATERIALS

The producers reported that approximately 52,755,253 short tons of raw materials (exclusive of fuels and explosives) entered into the manufacture of 164,030,559 barrels (30,837,745 short tons) of portland cement in the United States in 1941—an average of about 643 pounds to a barrel (376 pounds) of finished cement. The totals for 1941, with corresponding figures for 1940 (in parentheses) follow: 42,733,707 tons of limestone and cement rock (34,040,119 tons, revised figure); 4,726,192 tons of clay and shale (4,016,427 tons, revised figure); 659,201 tons of blast-furnace slag (581,873 tons); 1,066,635 tons of marl (932,339 tons); 1,035,179 tons of gypsum (807,938 tons, revised figure); and 2,534,339 tons of other materials, such as oystershells, sandstone, sand, cinders, fluorspar, iron ore, diatomaceous shale, pumicite, fuller's earth, bentonite, silica, quartz, ashes, pyrite ore, pyrite cinder, roll scale, calcium chloride, and hydrated lime (1,878,651 tons, revised figure).

FUELS AND POWER

Fuels.—According to monthly reports of producers, supplemented by a few estimates by the Bureau of Mines, the following quantities of fuel were consumed at portland-cement plants in the United States and Puerto Rico in 1941 in making 163,629,000 barrels of clinker (unground cement) and 164,030,559 barrels of finished cement: Coal, 6,831,825 short tons; oil, 3,552,030 barrels (42 gallons); and natural gas, 54,207,900,833 cubic feet. Corresponding figures for 1940 are: Clinker produced, 130,141,000 barrels, and finished cement produced, 130,216,511 barrels. Fuels consumed were: Coal, 5,633,156 short tons; oil, 2,424,976 barrels; and natural gas, 41,948,699,007 cubic feet.

The first and second of the accompanying tables on fuels compare the output of clinker and finished cement in 1940 and 1941 with the estimated fuel consumption by processes. Similar data were published in Statistical Appendix to Minerals Yearbook, 1935 (p. 200), covering 1933 and 1934. The third table on fuels shows detailed data on quantities used in 1940 and 1941.

Cement clinker (unground cement) produced and in stock at mills in the United States, 1940–41, by processes, in barrels of 376 pounds [1]

Process	Number of plants		Production		Stock (Dec. 31)	
	1940	1941	1940	1941	1940 [2]	1941 [3]
Wet	87	90	67,905,000	84,568,000	2,847,000	2,508,000
Dry	65	65	62,236,000	79,061,000	2,039,000	2,075,000
	152	155	130,141,000	163,629,000	4,886,000	4,583,000

[1] Compiled from monthly estimates of the producers.
[2] Revised figures.
[3] Subject to revision.

Portland cement burned and fuels used in the United States, 1940–41, by processes

Process	Finished cement produced			Fuel consumed [1]		
	Number of plants	Barrels of 376 pounds	Percent of total	Coal (short tons)	Oil (barrels of 42 gallons)	Natural gas (cubic feet)
1940

[2] Average consumption of fuel per barrel of cement produced was as follows: 1940—coal, 119.5 pounds; oil, 0.2174 barrel, natural gas, 1,561 cubic feet. 1941—coal, 118.7 pounds; oil, 0.2226 barrel; natural gas, 1,482 cubic feet
[3] In addition to the coal and natural gas included for this group, 1 plant reported the use of petroleum coke with coal and natural gas
[4] Includes 74,437 short tons of anthracite and 5,558,719 short tons of bituminous coal.
[5] In addition to the coal and natural gas included for this group, 2 plants reported the use of petroleum coke with coal and natural gas.
[6] Includes 96,768 short tons of anthracite and 6,735,057 short tons of bituminous coal

Electric power.—The accompanying table gives the electric energy produced at portland-cement plants and that purchased from power companies during 1940 and 1941. The cement industry generated 47 percent of its electric-power requirements in 1941 compared with 49 percent in 1940 and 50 percent in 1939.

Electric energy used at portland-cement-producing plants in the United States, 1940–41, by processes, in kilowatt-hours

Process	Electric energy used						Finished cement produced	Average electric energy used per barrel of cement produced
	Generated at portland-cement plants		Purchased		Total			
	Active plants	Kilowatt-hours	Active plants	Kilowatt-hours	Kilowatt-hours	Percent	Barrels	Kilowatt-hours

SPECIAL CEMENTS

In addition to the regular standard portland cements that constitute the great bulk of production, several special varieties of cement also are manufactured. They are designed to satisfy unusual demands, for instance, in high-early-strength cement where time is an important element; in low- and moderate-heat-of-hardening cement for monolithic structures; and in puzzolan cements for use in places where resistance to chemical attack is demanded. These and other special varieties were discussed in some detail in the chapter on Cement in Minerals Yearbook, Review of 1940 (pp. 1125–1127). Accordingly the discussion is restricted this year to data on certain masonry cements, the statistics for which do not appear in the accompanying table. The types referred to are certain masonry cements that are not true portlands but employ portland-cement clinker and finished portland cement as a base. To this base are added considerable quantities of lime or other constituents of various kinds. These specially prepared masonry cements are sold under proprietary names. Production, which was reported from 52 plants in 1941, totaled 3,097,382 barrels and shipments 3,080,605 barrels valued at $4,636,497—an average of $1.51 a barrel. Corresponding data for 1940, representing the output of 44 plants (revised figure) are: Production, 2,312,155 barrels, and shipments 2,260,636 barrels valued at $3,175,088—an average of $1.40 a barrel. As the finished portland cement and clinker used in making these types of masonry cement have been reported elsewhere by producers, to avoid duplication the above figures are not included in the totals.

The following table presents statistical data for recent years insofar as they are available covering special portland cements. All the figures except those for masonry cement (hydraulic but not portland) and "masonry natural" are included in the general tables earlier in this chapter.

Special portland cements produced and shipped in the United States, 1937–41, by kinds

Kind and year	Active plants	Production (barrels)	Shipments		
			Barrels	Value	
				Total	Average
High-early-strength					
1937	64	4,192,959	3,845,314	$7,134,468	$1.86

NEW DEVELOPMENTS

Large-scale rehabilitation and modernization programs are in progress or have been completed recently by at least six cement companies, and less extensive improvements have been made by many others. A large number of mills are now equipped with unit coal pulverizers that discharge directly into the kilns. This is one of the most outstanding recent improvements in plant design. Automatic control of all elements pertaining to the preparation of raw materials, calcination, and clinker grinding is attaining increased refinements, owing partly to the necessity of meeting exacting specifications and partly to the need for more efficient combustion and plant operation.

In certain localities the demand for cement has been so active that it is delivered on the job within a relatively short time after it is made. Consequently, some difficulty has been experienced because recent specifications in force at some consuming centers require cement to be delivered on the job at a temperature not higher than 125° F., whereas formerly 140° F. was allowed. At least one company has introduced the use of finished-cement coolers.

Other important developments include a wider use of cement-mill stack dust as a cement raw material and the introduction of a Lepol kiln at the plant of the Santa Cruz Portland Cement Co., Davenport, Calif. This installation is the second one of this type of equipment in the United States, the first being that of the Spokane Portland Cement Co., Irvin, Wash., introduced in 1935.

Further progress has been made in air-quenching hot clinker. The advantages are (1) reduction in grinding cost; (2) fuel conservation

(heat from the clinker being transferred to the kilns in a secondary air supply); and (3) improved quality of the cement as indicated by higher soundness tests.

Concrete ships gave unsatisfactory service in the World War of 1914–18, but their use has not been abandoned because of the failures of that period. They are again being built; and it is believed that those now under construction will give useful service, because the design has been improved, and the cement used is of higher quality than that which was available 25 years ago. The first concrete ships built during the present war were designed as tow barges, but more recently the Maritime Commission let contracts for 24 self-propelled seagoing craft, each of 5,200 tons. They will be built in a new shipyard at Tampa, Fla.

White cement is now used for the finishing coat on concrete floors in airplane factories. The reflected light from such floor surfaces is of great assistance to those constructing the underside of wings and fuselage.

Much progress has been made in the substitution of cement for iron, steel, or other metals urgently needed for military uses. The newer products include storage tanks for household oil burners, bleach tanks for laundries, septic tanks, bath tubs, and sash weights. A new type of manhole cover has been devised which requires only 15 to 20 pounds of reinforcing steel, whereas the ordinary 24-inch iron cover contains 85 to 100 pounds of metal.

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

The term "natural" is used to designate certain cements made by calcining argillaceous limestone at a comparatively low temperature and pulverizing the calcined material. Some of them have special properties that adapt them to mortar uses for laying brick and stone; therefore, they are classed as masonry (natural) cements.

Another special non-portland cement consists of a mixture of blast-furnace slag and hydrated lime. It is classed with the puzzolan cements.

Producers of these special non-portland cements reported that 48,091 short tons of coal and the gas equivalent of about 89 short tons of coal were used in their manufacture in 1941. Fuel consumed in 1940 totaled 42,873 short tons of coal and the gas equivalent of about 68 short tons of coal.

Production and shipments of these special types of cement combined are indicated in the following table.

Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1937–41

Year	Production		Shipments		Stock (Dec. 31)
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1937	12	1,900,643	1,873,400	$2,578,885	253,518
1938	12	1,820,795	1,867,949	2,725,776	373,816
1939	12	2,439,110	2,405,135	3,361,724	239,938
1940	12	2,534,566	2,514,597	3,386,801	[1] 259,868

TRENDS IN EMPLOYMENT AND OUTPUT PER MAN[1]

In Minerals Yearbook, 1935 (pp. 891–905) and 1940, Review of 1939 (pp. 1141–1153), trends in employment and output per man in the cement industry were traced from 1928 to 1938. The following data extend this 11-year period through 1939 and 1940.

GENERAL DATA

As may be noted in the first table, the number of men employed was greater in 1940 than in 1938 or 1939. The average number of days worked also was greater, but the average length of day has varied only slightly for several years. The average output of cement per man has increased progressively since 1937.

Employment in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1936–40

Year	Employment					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total				
1936	25,406	272	6,917,074	7.3	50,688,870	111,238,300	16.08	2.19	98.7
1937	26,432	279	7,380,028	7.4	54,714,935	116,174,708	15.74	2.12	100.0
1938	25,036	256	6,398,178	7.5	47,729,779	105,357,000	16.47	2.21	100.0
1939 [2]	25,503	273	6,974,191	7.3	51,184,194	121,934,911	17.48	2.38	99.7
1940 [2]	26,038	279	7,276,469	7.4	54,116,153	129,830,687	17.84	2.40	99.7

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production. [2] Exclusive of Puerto Rico.

MILL EMPLOYEES

In 1928 mill employees averaged 9.5 hours a day for 332 days and produced 1.98 barrels of finished cement per man-hour; in 1940 they averaged 7.4 hours a day for only 287 days but produced 2.95 barrels of cement per man-hour. Thus productivity per man per hour increased 49 percent during this 13-year period.

Mill employees in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1936–40

Year	Employment—cement mill only					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total				
1936	19,881	280	5,564,582	7.3	40,634,045	111,029,026	19.95	2.73	98.6
1937	20,925	289	6,041,237	7.4	44,553,173	116,174,708	19.23	2.61	100.0
1938	19,828	264	5,224,790	7.4	38,866,410	105,357,000	20.16	2.71	100.0
1939 [2]	20,186	282	5,691,718	7.3	41,518,750	121,934,911	21.42	2.94	99.7
1940 [2]	20,692	287	5,930,723	7.4	43,967,729	129,830,687	21.89	2.95	99.7

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production. [2] Exclusive of Puerto Rico.

[1] Statistics on employment and output per man presented in this discussion were compiled by E. T. Shuey from records of the employment statistics section, Bureau of Mines.

QUARRY AND CRUSHER EMPLOYEES

From 1929—the first year for which data are available—to 1940 the number of quarry and crusher employees dropped from 5,123 to 4,394, the average hours per day declined from 9.6 to 7.6, but the tonnage of material handled per man per hour increased from 3.20 to 4.14. This increase no doubt reflects increased mechanization and greater efficiency.

Quarry and crusher employees in the portland-cement industry, material (quarry rock and overburden) handled at quarries included in study, and average output of material per man in the United States, 1936–40

Year	Employment—quarry and crusher only					Material handled—quarry rock and overburden				Percent of industry represented[1]
	Average number of men	Time employed				Short tons	Percent of overburden included	Average per man (short tons)		
		Average number of days	Total man-shifts	Man-hours				Per shift	Per hour	
				Average per man per day	Total					
1936	5,023	246	1,233,219	7.4	9,174,710	(2)	(2)	(2)	(2)	98.7
1937	4,980	242	1,203,867	7.6	9,169,763	(2)	(2)	(2)	(2)	90.0

1940[3]	4,394	244	1,070,881	7.6	8,171,104	33,804,500	2.6	31.57	4.14	82.6

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production.
[2] Figures not available.
[3] Exclusive of Puerto Rico

HOURS PER DAY

A remarkable change has taken place in the average number of hours per day of employment. In 1928, 58 percent of the employees worked more than 9 hours a day; in 1940, only 2 percent. In 1928, 23 percent of the employees had a working day of 11 to 12 hours; in 1940, no employees worked more than 10 hours a day.

Number of men employed in the portland-cement industry in the United States and output per man-hour, 1938–40, classified according to hours of labor per day

Hours per day	1938			1939[1]			1940[1]		
	Men employed		Production per man-hour (barrels)	Men employed		Production per man-hour (barrels)	Men employed		Production per man-hour (barrels)

DISTRICT AND STATE TABLES

The following tables show a geographic break-down, by districts and States, of the statistical record of employment and productivity of labor in the cement industry. These data are primarily of interest in the study of regional relationships. The first table, covering employment in the portland-cement industry as a whole, and the second, relating to mill employees, give data for 1939 and 1940 supplementing similar figures for 1928 to 1933 in Minerals Yearbook, 1935 (pp. 897–902), and for 1934 to 1938 in Minerals Yearbook, 1940, Review of 1939 (pp. 1145–1152). The third table, comprising data for quarry and crusher employees in 1939 and 1940, supplements similar data for 1929 to 1933 in Minerals Yearbook, 1935 (pp. 903–905), and for 1934 in Minerals Yearbook, 1940, Review of 1939 (p. 1153); data for 1935 to 1938 are lacking.

Employment in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1939–40, by districts and by States (excluding Puerto Rico)

District and State	Employment					Production			Percent of industry represented[1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour

FOREIGN TRADE [2]

IMPORTS

The figures in the following table cover imports of hydraulic cements of all kinds. The values assigned represent those in the markets of the foreign countries from which the materials are exported, including the cost of containers or coverings. The second table shows imports by country of origin.

Hydraulic cement imported for consumption in the United States, 1937–41

Year	Barrels	Value	Year	Barrels	Value
1937	1,803,932	$1,392,633	1940	538,060	$506,191
1938	1,727,411	1,436,730	1941 (Jan.-Sept.)	43,110	57,914
1939	1,913,853	1,860,543			

Roman, portland, and other hydraulic cements imported for consumption in the United States, 1940–41, by countries [1]

Country	1940		1941 (Jan.-Sept.)	
	Barrels	Value	Barrels	Value
Belgium	325,937	$285,193		
Canada	2,058	4,755	417	$760
Denmark	81,848	81,635		
Italy	581	2,561		
Japan	23,364	25,241	14,367	16,078
Mexico	296	308		
Netherlands	9,000	7,070		
Norway	3,000	3,744		
United Kingdom	71,596	72,431	28,326	41,076
Yugoslavia	17,939	14,900		
	535,619	497,838	43,110	57,914

[1] Excludes "White, nonstaining, and other special cements."

EXPORTS

Although the United States is the major cement-producing country of the world, its export trade as indicated in the following table is small. The value of exports is the actual cost at United States ports, as indicated by the shippers on the export declarations.

Hydraulic cement exported from the United States, 1937–41

Year	Barrels	Value	Percent of total shipments from mills
1937	378,554	$1,044,161	0.3
1938	558,226	1,294,883	.5
1939	1,146,339	2,352,693	.9
1940	1,667,595	3,294,118	1.3
1941 (Jan.-Sept.)	1,757,172	3,793,511	1.0

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

STONE

By Oliver Bowles and M. S. Jensen

SUMMARY OUTLINE

GENERAL CONDITIONS

Sales of crushed and dimension stone combined continued their upward course, attaining an all-time record of 183,107,960 short tons in 1941 and exceeding sales of 1940 by 19 percent. The total value of sales was also the highest on record and topped 1940 by 22 percent. The dimension-stone industry, however, was less active than in 1940 because much of the construction during 1941 was of the war emergency type that requires relatively little building stone. Sales of dimension stone (exclusive of slate) were 8 percent lower in quantity and 0.1 percent lower in value. The crushed-stone industry, on the other hand, gained 19 percent in quantity and 25 percent in value of output in 1941.

The present chapter follows the general plan inaugurated in 1938, whereby the data on dimension stone are separated from those on crushed stone, except in the introductory general tables.

The tables of this report give the quantities sold or used by producers and the values f. o. b. quarries and mills insofar as these figures are obtainable. Stone quarried and used by producers is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show the total sales of stone by kinds, uses, and States.

Stone sold or used by producers in the United States, 1937–41, by kinds

[Quantities approximate]

Year	Granite		Basalt and related rocks (trap rock)		Marble		Limestone	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1937	9,265,830	$20,192,882	13,581,460	$12,508,276	207,760	$5,456,191	94,577,270	$90,901,877
1938	10,432,980	20,915,609	13,908,790	12,280,016	219,390	5,248,290	81,679,690	82,286,555
1939	12,041,360	22,495,983	16,091,250	14,164,016	228,080	6,688,662	100,846,090	94,817,481

DIMENSION STONE

The term "dimension stone" is applied to blocks or slabs of natural stone, most of which are cut to definite shapes and sizes. These products are quite distinct from crushed, broken, and pulverized stone, which comprises irregular fragments or grains sized chiefly by mechanical screening or air separation. Crushed and broken stone is covered in a later section of this chapter.

Dimension-stone producers may be divided into three main groups upon the basis of plant operation. The first group quarries stone and sells it as rough blocks or slabs; the second quarries stone and also manufactures it into finished products; and the third buys sawed slabs or rough blocks of stone and manufactures them into finished products but does not operate quarries. The Bureau of Mines statistical canvass covers the first and second groups, but as the third group comprises manufacturers rather than quarrymen it is canvassed by the Bureau of the Census. Bureau of Mines statistics are compiled from reports of quantities and values of original sales; hence they include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone in 1941 declined 6 percent in quantity but gained 4 percent in value compared with 1940. These figures include slate, but details of the slate industry are given in the separate chapter on Slate. Dimension marble, limestone, and basalt declined substantially in both quantity and value, but granite, sandstone, and miscellaneous stone registered gains.

The following table of salient statistics for dimension stone includes figures for 1940 and 1941, as well as the percentage change from 1940 for each type of stone by principal products.

Dimension stone sold or used by producers in the United States, 1940–41, by kinds and uses

Kind and use	1940	1941 Total	1941 Percent of change
Granite:			
Building stone:			
Rough construction ... short tons	89,040	167,440	+88.1
Value	$245,385	$298,253	+21.5

Value	$24,853,278	$25,805,668	+3.8

[1] To avoid disclosing confidential information, paving blocks in 1941 are included under "Curbing."
[2] Includes soapstone, mica schist, volcanic rocks, argillite, and other varieties that cannot be classified in the principal groups.
[3] Details of production, by uses, are given in the chapter on Slate in this volume.

BUILDING STONE

The largest use of dimension stone is for building. The following table gives the quantity and value of each kind of stone used for construction in 1941.

Building stone sold or used by producers in the United States in 1941, by kinds

Kind	Rough			
	Construction		Architectural	
	Cubic feet	Value	Cubic feet	Value
Granite	2,034,920	$298,253	433,350	$514,585
Basalt	108,510	17,182		
Marble			98,800	239,376
Limestone	1,319,870	367,995	1,651,910	666,323
Sandstone	402,520	106,426	256,740	202,165
Miscellaneous	870,800	916,735		
	4,736,620	1,706,591	2,440,800	1,622,449

Kind	Finished				Total	
	Sawed [1]		Cut [1]			
	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value
Granite	83,580	$304,338	219,800	$1,034,280	2,771,650	$2,151,456

Sandstone	212,450	252,612	43,650	145,096	915,360	706,299
Miscellaneous					870,800	916,735
	1,534,470	1,482,619	1,620,970	5,006,308	10,332,860	9,817,967

[1] For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.

GRANITE

Sales of block granite increased 19 percent in quantity and 7 percent in value in 1941 compared with 1940. Sales of rough architectural and dressed building stone declined greatly; but the cruder forms of building stone—namely, rubble and rough construction stone—made important gains. Net losses in the construction field were more than compensated by substantial gains in sales of both rough and dressed monumental stone. The value per cubic foot of dressed building stone increased from $4.31 in 1940 to $4.41 in 1941, and the value of dressed monumental stone increased from $6.04 to $6.35. The number of paving blocks sold in 1941 increased 31 percent over the number in 1940, but the quantity of curbing sold declined 7 percent. The unit value of paving blocks receded, but that of curbing advanced.

Granite (dimension stone) sold or used by producers in the United States in 1941, by States and uses

Average daily wage	$8.50	$8.50	$9.00
Average number of days worked	220	220	230
Total pay roll for year	$2,898,500	$2,421,650	$3,729,600
Estimated overhead	1,449,250	1,210,825	1,864,800
Estimated value of light stock	1,247,714	1,199,651	1,398,605
Estimated value of dark stock	990,494	874,033	1,097,367
Estimated polishing cost	388,039	346,980	422,988
Output from saws	129,546	115,660	140,996
Total value of granite	7,104,143	6,168,799	8,654,356

[1] Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen.

BASALT AND RELATED ROCKS (TRAP ROCK)

Because of its dark color, basalt is not used extensively for building. The tonnage sold in 1941 was less than one-half that in 1940, but the value per ton increased from 95 cents to $1.72. In 1939 considerable quantities were used for rubble, but this use declined greatly in 1940 and almost disappeared in 1941. Some of these dark rocks are used for memorials, but such stones are classed commercially as black granites and are therefore included with the figures for monumental granite.

Basalt and related rocks (trap rock) (dimension stone) sold or used by producers in the United States in 1941, by States and uses

State	Active plants	Building stone				Total	
		Rough construction		Rubble			
		Short tons	Value	Short tons	Value	Short tons	Value
California	1			30	$400	30	$400
Connecticut	3	3,420	$3,325			3,420	3,325
New Jersey	1	110	110			110	110
Oregon	1	2,260	9,248			2,260	9,248

	9	[1] 10,170	17,182	130	550	10,300	17,732
Average unit value			$1.69		$4 23		$1.72

[1] 108,510 cubic feet (approximate).

MARBLE

Sales of dimension marble in 1941 declined 22 percent in quantity and 9 percent in value compared with 1940. Large declines in sales of building marble were compensated to some extent by general increases in sales of monumental marble, which depend primarily on buying power. Decreases in total quantities sold were shared by all the leading States except Georgia, although the value of sales was higher in Vermont and Utah than in 1940.

Marble (dimension stone) sold by producers in the United States, 1940–41, by uses

Use	1940		1941	
	Cubic feet	Value	Cubic feet	Value

[1] Includes 4,720 cubic feet of serpentine marble (verde antique) valued at $34,101, which was sold as building and ornamental stone.
[2] Included under "Undistributed."
[3] Figures represent onyx rough blocks for the manufacture of mantels, lamp bases, desk sets, clock cases, and novelties.
[4] Average value per cubic foot.

LIMESTONE

Unlike granite and marble, of which substantial quantities are sold for memorial uses, block limestone is employed almost exclusively as building stone. Limestone is used in the United States more extensively than any other type of building stone, and Indiana producers supplied about 76 percent of the rough architectural and finished (sawed and cut) limestone sold in 1941. The total quantity of dimension limestone sold in 1941 was 25 percent less and its value 11 percent less than in 1940.

Rough building limestone sold made only a small gain in quantity, but the sales value was more than twice that in 1940. All other types of building limestone suffered serious declines because during a war emergency construction of buildings using stone as a major material is greatly restricted. Sales of flagging declined moderately in 1941.

Limestone (dimension stone) sold or used by producers in the United States in 1941, by States and uses

[1] Revised figures.

SANDSTONE

Sales of dimension sandstone increased 6 percent in quantity in 1941 compared with 1940 but remained almost the same in value. Figures for sandstone used for rough construction, for rough architectural building purposes, as rubble, and for curbing show small changes from those of the corresponding classifications in 1940. Sales of sawed stone advanced, but those of cut stone declined. The largest gains were in sales of flagging. Paving-stone production, once an important branch of the industry, has declined almost to the vanishing point.

The second table following presents a 20-year history of the bluestone industry. This type of sandstone is used for building stone and for curbing and flagging. As "sidewalk stone" it has been replaced generally by concrete, but this loss of market has been compensated to some extent by enlarged demands for ornamental flagging. Sales in 1941 were 11 percent higher in quantity but 7 percent lower in value than in 1940.

[2] Includes 169,520 cubic feet of bluestone (approximately 14,320 short tons) valued at $172,329 sold for construction, curbing, and flagging.
[3] Includes a small quantity of paving blocks.
[4] Includes 114,670 cubic feet of bluestone (approximately 9,690 short tons) valued at $79,984 sold for construction, curbing, and flagging.
[5] 402,520 cubic feet (approximate).

Bluestone (dimension stone) sold or used in the United States, 1922–41[1]

Year	Cubic feet	Value	Year	Cubic feet	Value
1922	722,830	$697,341	1932	185,960	$185,643
1923	618,360	747,422	1933	116,246	123,867
1924	769,240	875,734	1934	181,960	168,720
1925	987,300	910,585	1935	215,150	203,537
1926	692,640	885,597	1936	343,040	332,749
1927	815,730	1,000,217	1937	308,740	346,349
1928	891,190	1,014,843	1938	329,670	369,857
1929	670,020	773,532	1939	254,440	319,405
1930	611,240	749,703	1940	256,900	272,501
1931	356,210	427,801	1941	284,190	252,313

[1] New York and Pennsylvania are the only States that produce bluestone.

MISCELLANEOUS STONE

The following table gives data on certain types of dimension stone not included in the major groups already discussed. The principal varieties are mica schist, argillite, various light-color volcanic rocks, soapstone, and greenstone. The quantity sold in 1941 increased 6 percent and the value 17 percent over 1940.

Miscellaneous varieities of stone (dimension stone) sold or used by producers in the United States in 1941, by States and uses

State	Active plants	Building: Rough and dressed		Building: Rubble		Flagging		Total	
		Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
California	1	(1)	(1)	(1)	(1)			(1)	(1)

Average unit value			$12.49		$2.79		$5.44		$10.91

[1] Included under "Undistributed."
[2] Building stone (rough and dressed), approximately 870,800 cubic feet; flagging, approximately 36,930 cubic feet.

TRENDS IN USE OF DIMENSION STONE

Figure 1 shows graphically the history of production of dimension stone, by kinds, for a 26-year period. Dimension stone includes all classes of building stone, as well as memorial stone, paving blocks, curbing, and flagging. Limestone and granite are the leading varieties. All kinds of dimension stone follow essentially the same pattern throughout both lean and prosperous years.

Figure 2 traces the history of production of all building stones and of the principal variety—limestone—in their relation to nonresidential building, the class of construction using stone most extensively. Stone is a dignified, substantial, and enduring building material that is used chiefly in permanent and relatively costly structures. The necessities of war stimulate enormous building

497779—43——80

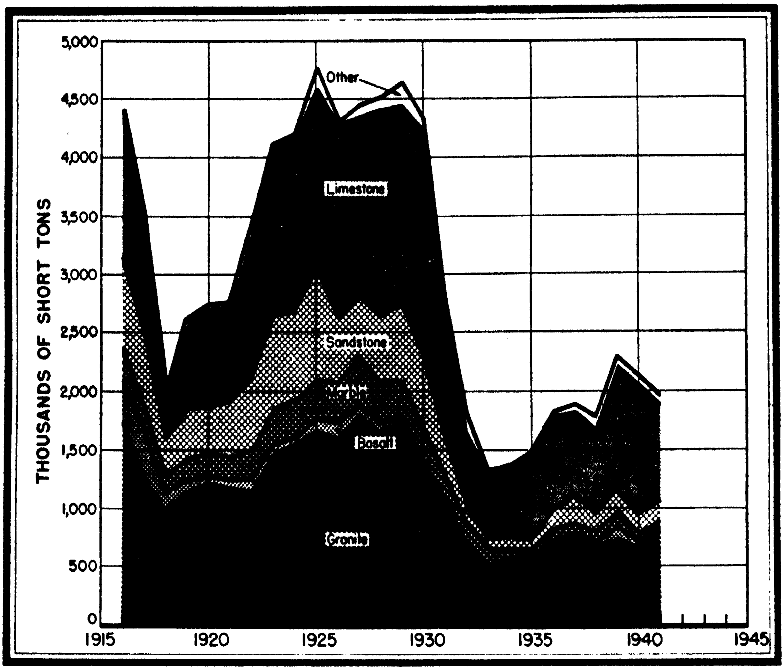

FIGURE 1.—Sales of dimension stone in the United States, by kinds, 1916–41.

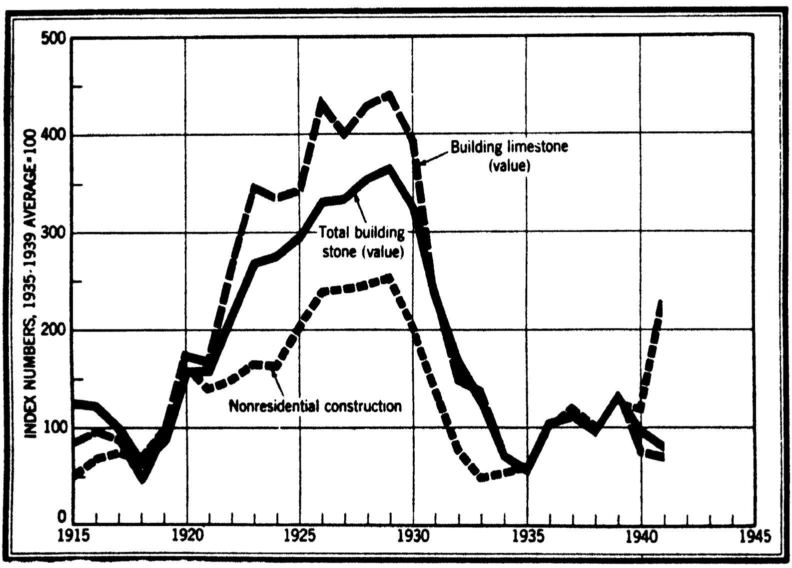

FIGURE 2.—Sales of all building stone and building limestone compared with nonresidential construction (public and private), 1915–41. Data on nonresidential building construction from Bureau of Foreign and Domestic Commerce.

programs, but the types of construction demanded for such emergencies employ only limited quantities of dimension stone. As indicated in figure 2, wars and depressions are inimical to activity in the building-stone industries which flourish during eras of peace and general prosperity. Building-stone sales fell to a low point in 1918 at the close of the First World War; but they recovered rapidly and, upon the basis of the 1935–39 averages, attained much higher levels than nonresidential building (public plus private) during the prosperous years 1926–29. Sales of stone followed closely the rapid decline in nonresidential building during the depression years that followed. Although building has recovered substantially since 1935, stone has made only moderate gains, and the Second World War has depressed activity to an exceptional extent.

NEW DEVELOPMENTS

No important new developments were reported by the dimension-stone industries during 1941. One new marble quarry was opened near Bainbridge, Pa. In general, the demands for building and memorial stone were so limited that some units of unused machinery and facilities were diverted to the manufacture of war materials.

The Bureau of Mines has issued an index to locations of stone quarries.[1] It is not a directory but indicates the kinds of stone quarried, by States and counties.

CRUSHED AND BROKEN STONE

Over 181,000,000 short tons of crushed and broken stone were sold in 1941, exclusive of that used for making cement and lime. Sales increased 19 percent in quantity and 25 percent in value compared with 1940.

The following table of salient statistics shows the quantity and value of crushed and broken stone sold during 1940 and 1941, by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters on Asphalt and Slate.

[2] To avoid disclosing confidential information certain totals are somewhat incomplete, the figures not included being combined under "Undistributed."

GEOGRAPHIC DISTRIBUTION OF PLANTS

Figure 3 shows the location of quarries in the United States producing concrete aggregate and road stone. Limestone quarries abound in the Appalachian Mountain area of the Eastern and Southeastern States. Granite quarries predominate in New England and are plentiful in other Eastern States. Trap rock is important in New Jersey, New York, and parts of New England.

In the Middle Western States limestone quarries predominate, but those in other kinds of rock are scattered widely, notably in the granites of the Northern States. Throughout the Rocky Mountain area quarries are relatively few; on the Pacific coast most are in rocks other than limestone.

Quarries are most numerous in the thickly populated areas of the Eastern, Middle Western, and Pacific Coast States because large demands for highways and buildings have fostered the development of many producing units. Our stone resources are enormous and widely distributed. Their development depends primarily on local market demands. Stone is available within reasonable reach of virtually every important market area.

Commercial and noncommercial operations.—The following table shows the production of crushed stone for concrete and road metal and railroad ballast during recent years by Government agencies of various kinds contrasted with that by commercial enterprises. Production by commercial companies increased 37 percent in 1941 compared with 1940, whereas production by Government agencies declined 7 percent. Seventy-one percent of the total production was made by commercial companies.

Concrete and road metal and railroad ballast sold or used by commercial and noncommercial operators in the United States, 1937–41

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers]

Year	Commercial operations				Noncommercial operations				Total	
	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Percent of change in quantity from preceding year
1937	62,315,350	$0 88	+8 4	70 5	26,117,220	$1 06	−12 3	29 5	88,432,570	+1 3
1938	60,254,170	.88	−3 3	63 6	34,508,880	1 04	+32 1	36 4	94,763,050	+7 2
1939	59,516,270	86	−1 2	57 3	44,374,750	97	+28 6	42 7	103,891,020	+9 6
1940	63,203,240	.87	+6 2	63 0	37,065,150	1 02	−16 5	37 0	100,268,390	−3.5
1941	86,360,120	.91	+36 6	71 4	34,603,790	1 04	−6 6	28.6	120,963,910	−20.6

Methods of transportation.—The following table shows the quantities of concrete and road metal conveyed during 1940 and 1941 by each of the principal methods of transportation.

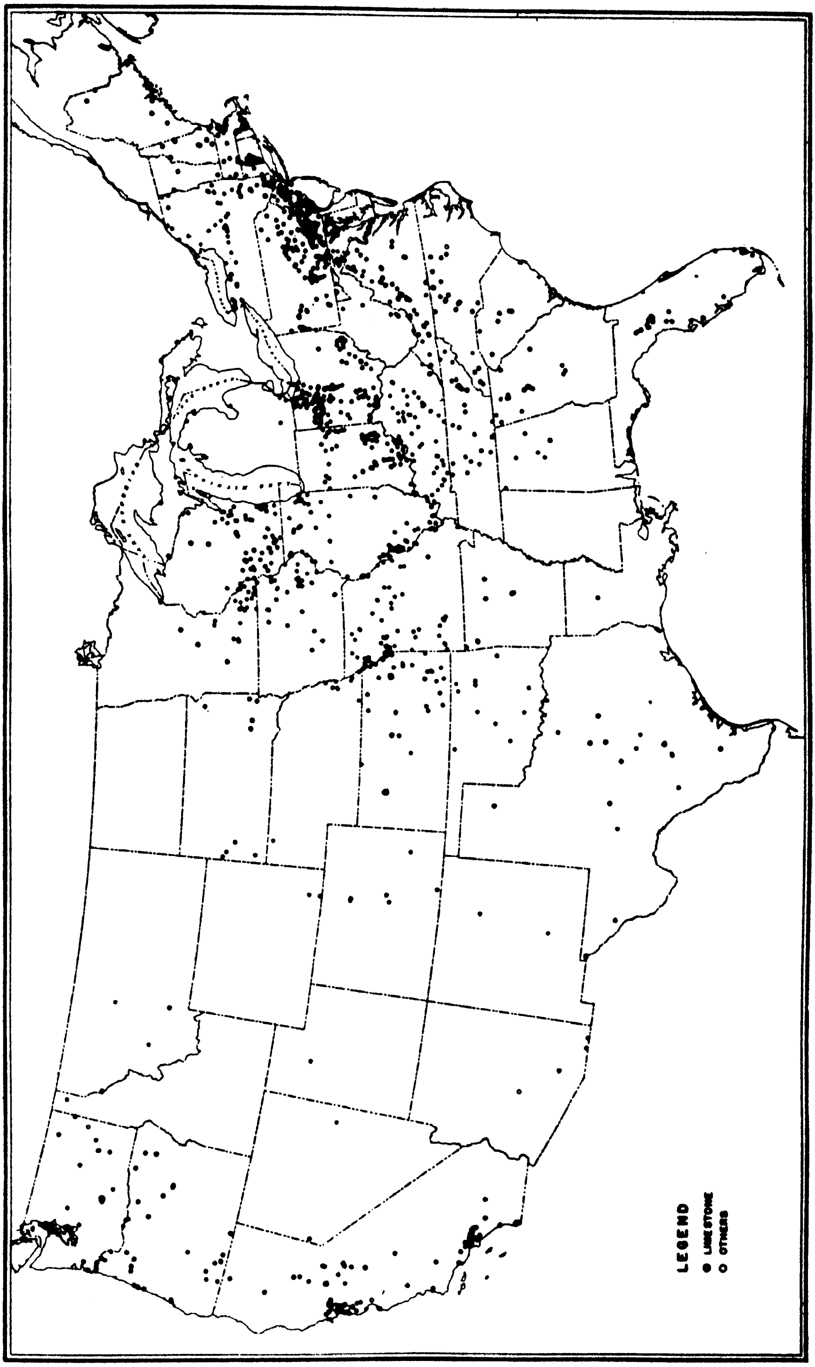

FIGURE 3.—Distribution of stone quarries producing aggregate and road stone in the United States.

Concrete and road metal sold or used by commercial producers in the United States, 1940–41, by methods of transportation [1]

Method of transportation	1940		1941	
	Short tons	Percent of total	Short tons	Percent of total
Truck	36,069,110	64.7	49,107,430	65.0
Rail	10,911,260	19.5	18,047,780	23.9
Waterway	6,072,270	11.0	4,690,770	6.2
Unspecified	2,696,300	4.8	3,742,840	4.9
	55,748,940	100.0	75,588,820	100.0

[1] For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, crushed stone for concrete and road metal moved as follows—1940: Truck 79 percent, rail 12 percent, waterway 6 percent, and unspecified 3 percent; 1941: Truck 76 percent, rail 16 percent, waterway 4 percent, and unspecified 4 percent.

GRANITE

Sales of crushed and broken granite increased 32 percent in quantity and 23 percent in value in 1941 compared with 1940. Sales of riprap were 2½ times those in 1940. Such sales commonly fluctuate greatly, as they depend chiefly on special reclamation or other projects.

Noncommercial production, which is a substantial part of the total, is reported by city, county, and State governments, highway commissions, or other Government agencies. Because the number of individual operations supplying noncommercial crushed stone cannot be determined with any degree of accuracy from the reports submitted, the columns indicating the number of active plants (which have appeared in the granite and other tables covering the crushed-stone industry for many years before 1939) have been omitted in the reports covering 1939, 1940, and 1941.

Granite (crushed and broken stone) sold or used by producers in the United States in 1941, by States and uses

[1] Includes stone used for artificial stone, asphalt filler, chips, fill material, poultry grit, road base, spalls, stone sand, and terrazzo.
[2] Included under "Undistributed."

BASALT AND RELATED ROCKS (TRAP ROCK)

Basalt, gabbro, diorite, and other dark igneous rocks (known commercially as trap rock) are used widely for highway construction and concrete aggregate. Sales of crushed and broken trap rock increased 14 percent in quantity and 23 percent in total value in 1941 compared with 1940, and the average value per ton increased from 97 cents to $1.04.

Sales of material classed as riprap, which suffered a marked decline in 1940, continued to move downward in 1941; projects using riprap probably are regarded as less essential than many others during the present war emergency. Stone used as concrete aggregate and for road construction increased 14 percent in quantity and 19 percent in value. Sales of trap rock for railroad ballast and for miscellaneous uses increased more than 60 percent.

Basalt and related rocks (trap rock) (crushed and broken stone) sold or used by producers in the United States in 1941, by States and uses

[1] Includes stone sold for fill material, roofing granules, and unspecified uses.
[2] Included under "Undistributed."

MARBLE

Marble producers accumulate large quantities of waste material, consisting either of defective blocks or of cuttings and spalls that result from marble dressing, and they are constantly seeking profitable outlets for this waste. As the following table indicates, the price per ton realized varies greatly, because some States produce relatively high priced commodities, such as terrazzo, stucco, and marble flour, that may be worth several dollars a ton, whereas other States find outlets only in the form of riprap, road stone, and concrete aggregate that may command prices of only $1 or less a ton.

Marble (crushed and broken stone) sold by producers in the United States in 1941, by States [1]

LIMESTONE

Limestone is used more widely for crushed and broken stone than any other rock, because it can be quarried and crushed at moderate cost, is available to a multitude of markets, and is essential to many chemical and manufacturing industries. In 1941 limestone constituted 73 percent of all crushed and broken stone sold (excluding that used for making cement and lime). Sales in 1941 were 19 percent higher in quantity and 25 percent higher in value than in 1940.

The following tables show production by States and uses in 1941 and sales for miscellaneous industrial uses in 1940 and 1941.

Limestone (crushed and broken stone) sold or used by producers in the United States in 1941, by States and uses

	10,731,990	10,629,560	12,303,830	13,788,732

[1] Includes stone for filler for calcimine, caulking compounds, cosmetics, explosives, imitation leather, linoleum, paint, paper, parting compounds, phonograph records, plastics, pottery, putty, regrinding, roofing, rubber, sealing wax, tile, tooth powder, wire, and unspecified uses.
[2] Includes stone for acid neutralization, carbon dioxide, chemicals (unspecified), concrete blocks and pipes, dye, foundry facings, motion-picture snow, oil wells, rayon, rice milling, spalls, and spray.

Sales of dolomite (calcium-magnesium carbonate) and its primary product of calcination—dolomitic lime—for certain special uses are covered in the following table:

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1940–41

	1940	1941
Dolomite for—		
Basic magnesium carbonate:		
Short tons	80,210	105,670
Value	$105,028	$136,180
Dead-burned dolomite or refractory stone:		
Short tons	857,950	980,190
Value	$632,582	$729,792
Dolomitic lime for—		
Refractory (dead-burned dolomite):		
Short tons	867,909	1,069,887
Value	$6,925,328	$9,111,172
Paper mills:		
Short tons	59,000	78,000
Value	$390,000	$551,000
Total (calculated as raw stone) ... short tons	2,792,000	3,382,000

Limestone is quarried not only for use raw but also for manufacture into cement and lime. The large and important industries manufacturing these products are covered in separate chapters. It is of interest, however, to show in one table, as follows, the total tonnage of limestone consumed for all purposes.

Limestone sold or used for all purposes in the United States, 1939–41, in short tons

Use	1939	1940	1941
Limestone (as given in this report) (approximate)	100,846,000	112,658,000	133,164,000
Portland cement (including "cement rock") [1] Natural cement ("cement rock") [1]	30,463,000	[2] 34,041,000	42,735,000
Lime [3]	8,509,000	9,774,000	12,159,000
	139,818,000	[2] 156,473,000	188,058,000

[1] Reported in terms of cement in chapter on Cement.
[2] Revised figures.
[3] Reported in terms of lime in chapter on Lime.

SANDSTONE

The crushed-sandstone industry made substantial gains in 1938 and 1939, receded in 1940, and advanced in 1941, when sales were 17 percent higher in quantity and 32 percent higher in value than in 1940. Unusual activity in steel plants was indicated by a 45-percent increase in sales of refractory stone (ganister). Sales of riprap were more than twice those in 1940, and the output of aggregates, road stone, and railroad ballast made large gains. Sales of sandstone applied to various miscellaneous uses dropped to about one-third their 1940 volume.

The average value per ton of refractory stone increased from $1.80 to $1.89; of riprap from 84 to 99 cents; and of aggregates from $1.07 to $1.19. Railroad ballast, however, declined from 90 to 85 cents a ton. The average sales value at the mill or quarry for all crushed sandstone was $1.26 a ton in 1941, whereas it was $1.12 in 1940.

Sandstone (crushed and broken stone) sold or used by producers in the United States in 1941, by States and uses

State	Refractory stone (ganister)		Riprap		Crushed stone				Other uses [1]		Total

[1] Includes sandstone used for fill material, manufacture of spun glass, poultry grit, rock dust, rock wool, roofing granules, and stone sand.
[2] Included under "Undistributed."

MISCELLANEOUS STONE

Crushed and broken stone, other than the five principal varieties already discussed, includes light-color volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows sales of stone of these types, by States and uses, in 1941; such sales increased 29 percent in quantity and 34 percent in value over 1940.

Miscellaneous varieties of stone (crushed and broken stone) sold or used by producers in the United States in 1941, by States and uses

State	Riprap		Crushed stone				Other uses [1]		Total	
			Concrete and road metal		Railroad ballast

Average unit value		$0.97		$0.74		$0.45		$1.38		$0.77

[1] Includes stone used for filler (unspecified), poultry grit, refractory, road base, rock wool, roofing granules, stucco, tennis courts, and terrazzo.
[2] Included under "Undistributed."

MARKETS

As indicated in figure 4, sales of crushed stone have maintained a reasonably close relation to total building construction and cement shipments during recent years. Concrete pavements which consist of stone and cement naturally follow the same general trends. However, sales of stone fell below pavement construction from 1932 to 1937 but attained relatively higher levels during the following years.

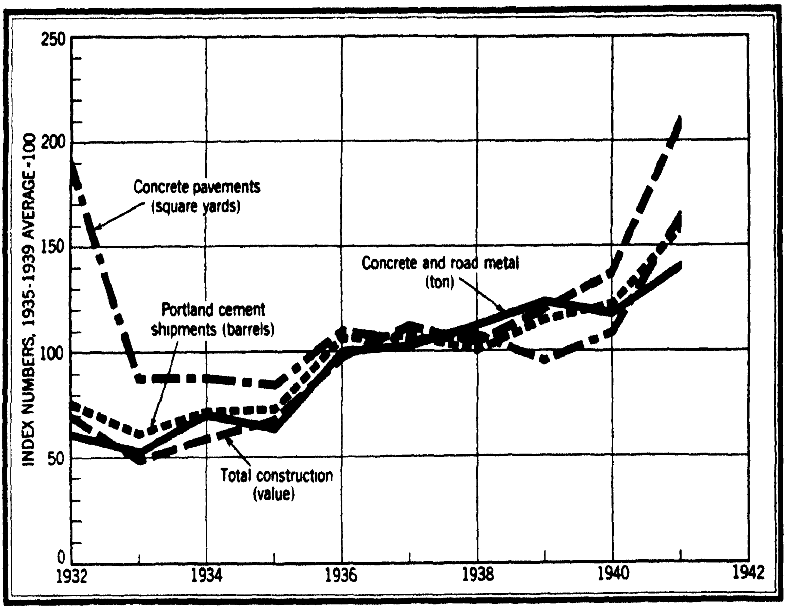

FIGURE 4.—Crushed-stone aggregates (concrete and road metal) sold or used in the United States compared with shipments of portland cement, total construction (value), and concrete pavements (contract awards, thousands of square yards), 1932–41. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

Pig-iron production reached phenomenal heights in 1941, and in consonance therewith sales of limestone used as furnace flux were the highest on record. Moreover, steel mills were everywhere producing ingots at almost maximum capacity, and naturally large quantities of dolomite and ganister were needed to make furnace linings. Forcing steel furnaces to increase their output placed an unusual demand on producers of refractories. The relations of fluxing-stone output to pig-iron production and of refractory stone to steel-ingot manufacture over a 10-year period are indicated in figure 5.

NEW DEVELOPMENTS

Several new, highly efficient, crushed-stone plants were completed during 1941. New equipment was added to several plants, and considerable rehabilitation was accomplished before such programs were interrupted by priority requirements.

Construction of the Delaware Aqueduct designed to supplement the water supply of New York City has created the unique situation of the project furnishing its own crushed stone. Large temporary crushing plants have been established to reduce the stone removed during excavation of the tunnels. The crushed stone is used as aggregate in the concrete structures of the aqueduct.

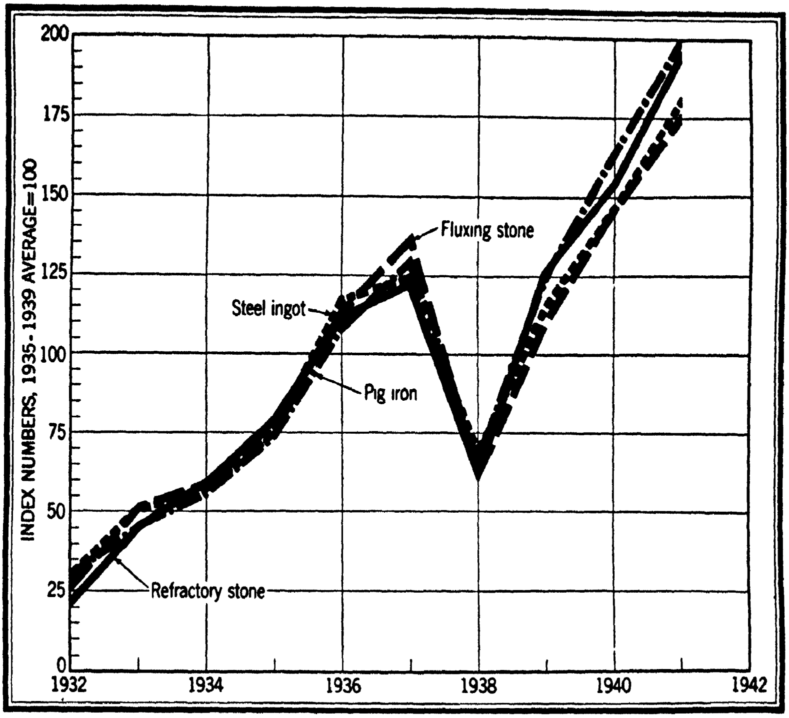

FIGURE 5.—Sales (tons) of fluxing stone and refractory stone including that used in making lime as recorded in the chapter on Lime compared with production of steel ingot and pig iron, 1932–41. Statistics of steel-ingot and pig-iron production compiled by American Iron and Steel Institute.

The most striking new development in the stone industries is the newly awakened interest in dolomite as a source of magnesium metal, of which large quantities are in demand for military equipment. Added to this new and outstanding use are many other industrial applications; the most important is the greatly increasing demand for refractory dolomite used in lining steel furnaces. To supply an insistent call for information on dolomite deposits, the Bureau of Mines prepared a report[2] which appeared in November 1941. Because of the growing demand for more details concerning the dolomites of the United States, a supplementary report giving the location, extent, and chemical analyses of many deposits was in preparation early in 1942.

[2] Colby, Shirley F., Occurrences and Uses of Dolomite in the United States: Bureau of Mines Inf. Circ. 7192, 1941, 21 pp.

FOREIGN TRADE[3]

Exports.—The export trade in stone is relatively small.

Stone exported from the United States, 1937–41

Year	Marble and other building and monumental stone		Other manufactures of stone (value)	Year	Marble and other building and monumental stone		Other manufactures of stone (value)
	Cubic feet	Value			Cubic feet	Value	
1937	[1] 79,456	[1] $145,454	[2] $631,856	1940	77,896	$158,008	$264,949
1938	78,374	141,815	282,422	1941 (Jan.-Sept.)	54,062	108,706	289,860
1939	77,147	134,416	366,004				

[1] Separately classified as—Marble in blocks, rough or dressed: 19,384 cubic feet valued at $88,528; other building and monumental stone: 60,072 cubic feet valued at $56,926.
[2] Separately classified as—Marble, breccia, and onyx, $33,307; limestone, $201,580; other manufactures of stone, $396,969.

Imports.—Owing to military restrictions, imports in 1941 can be published for only the first 9 months. As might be inferred from the far-reaching and intensified effects of the war, imports of stone were very small; from sources outside the American Continent they were almost negligible.

Stone imported for consumption in the United States in 1941 (January–September, inclusive), by classes

Class	Quantity	Value	Class	Quantity	Value
Marble, breccia, and onyx:			Quartzite.....short tons..	62,048	$111,055

SLATE

By Oliver Bowles and M. S. Jensen

SUMMARY OUTLINE

Sales of slate as dimension stone increased 17 percent in quantity and 28 percent in value in 1941 compared with 1940. Sales were approximately the same in quantity as in 1939, but the value was considerably higher. In nearly all categories unit prices were substantially higher than in 1940.

Roofing-slate sales gained 9 percent in quantity over 1940 but were still much lower than in 1939. The value of sales, however, was the highest in any year since 1930. The average value per square in 1941 was $8.39, whereas in 1940 it was $7.02. Sales in the Pennsylvania area were 15 percent higher in quantity and 44 percent higher in value than in 1940. In the New York-Vermont area sales declined 4 percent in quantity but gained 10 percent in value. Virginia sales increased 6 percent in quantity and 15 percent in value.

Sales of mill stock increased 4 percent in quantity and 15 percent in value compared with 1940. Although total new construction increased from 137 percent of the 1935–39 average in 1940 to 208 percent in 1941, sales of structural and sanitary slate declined 1 percent, indicating a growing trend toward substitution of other materials. Sales of electrical slate (reflecting the rapidly increasing electric-power output) increased 43 percent in quantity and 50 percent in value and reached the highest level of output since 1930. Sales of vaults and covers show little change from 1940—a gain of 2 percent in quantity and of 9 percent in value. Sales of blackboards and bulletin boards, which have declined sharply during the past 2 years, were the lowest since 1934. The year 1941 showed a 16-percent decrease in quantity and 14-percent in value compared with 1940. Sales of billiard-table tops, which in 1940 attained the highest level since 1928, receded slightly in 1941—1 percent in quantity and 11 percent in value. Sales of school slates increased 26 percent in quantity and 42 percent in value. Both the quantity and value of flagstones and stepping stones were more than twice those in 1940.

Statistics on slate granules and flour are included in this chapter, although these products have little connection with the dimension-slate industry except that granules are used in roofing products that compete in the roofing-slate market. For the most part, slate used for the manufacture of granules is unsuitable for other slate products. Sales of granules increased 40 percent in quantity and 35 percent in value and sales of flour 29 percent in quantity and 36 percent in value compared with 1940. The great increase in sales of granules probably reflects the extensive program of building military camps and other more or less temporary structures in connection with the preparedness program. The average sales value of granules f. o. b. mill was $8.37

and flour $3.49 per short ton in 1941 compared with $8.72 and $3.31, respectively, in 1940. Figures for sales of granules made of rock other than slate are given in the chapter of this volume on Stone.

The following table, presenting the principal statistical data for the slate industry during 1940 and 1941, is arranged to permit ready comparison of the 2 years.

Salient statistics of the slate industry in the United States, 1940–41

SALES

Dimension slate.—All slate products except granules and flour are classed as dimension slate because they consists of blocks or slabs cut to specified sizes and shapes. The following table shows sales of these products for a 5-year period.

Slate (other than granules and flour) sold by producers in the United States, 1937–41

Year	Roofing			Mill stock		Other [1]		Total	
	Squares	Approximate equivalent short tons	Value	Approximate short tons	Value	Approximate short tons	Value	Approximate short tons	Value
1937	365, 800	137, 400	$2, 728, 109	21, 480	$1, 225, 645	8, 670	$73, 554	167, 550	$4, 027, 308
1938	322, 040	119, 590	2, 247, 910	16, 310	853, 602	7, 790	63, 839	143, 690	3, 165, 351
1939	399, 320	149, 410	2, 868, 961	21, 710	1, 168, 671	8, 480	63, 493	179, 600	4, 101, 125

1941	378, 980	140, 830	3, 180, 766	18, 680	1, 076, 814	21, 480	152, 254	180, 990	4, 409, 834

[1] Includes flagstones, walkways, stepping stones, and miscellaneous slate.

Figure 1 compares sales of roofing slate, as well as all slate except granules and flour, with the number of new residential units and total

new construction from 1920 to 1941. Roofing slate is used principally in residential construction, but mill stock such as structural and sanitary products is used more generally in nonresidential building. Roofing slate failed to pace new residential building from 1921 to 1929, but thereafter both maintained a fairly uniform slow tempo until 1938.

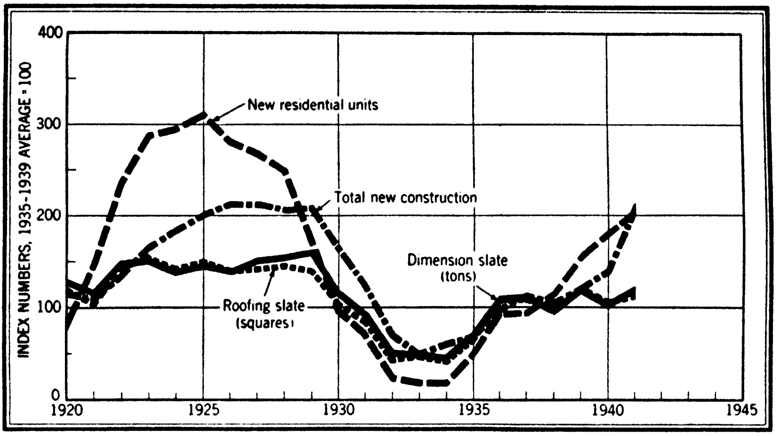

FIGURE 1.—Sales of dimension slate and roofing slate compared with total new construction and new residential units, 1920–41. Data on new construction from Bureau of Foreign and Domestic Commerce and on new residential units from Bureau of Labor Statistics.

From 1939 to 1941 new residential units increased greatly, but roofing slate made relatively small gains. The same general relationships hold when total dimension slate is compared with total new construction.

Figure 2 presents graphically a statistical history of all slate products except school slates over a 27-year period. The industry reached

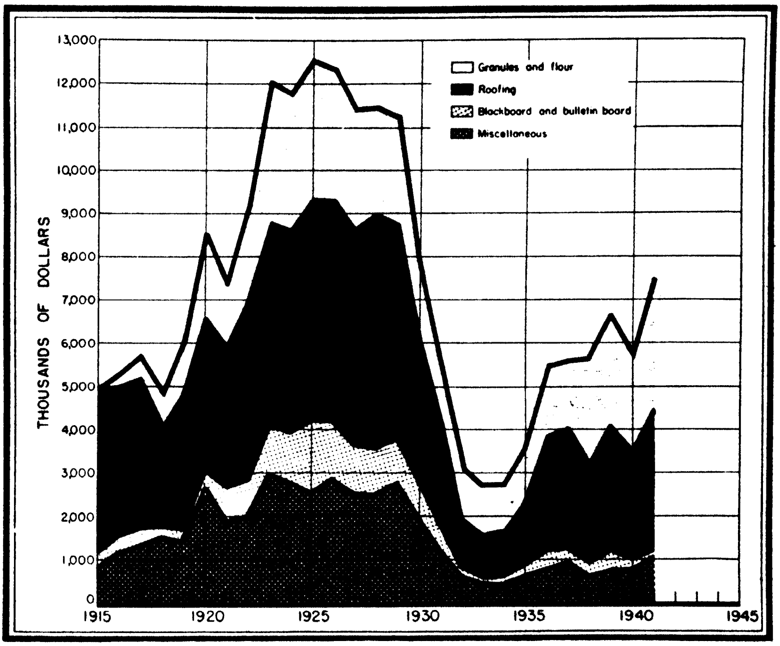

FIGURE 2.—Value of slate sold in the United States, 1915–41, by uses.

its peak of productive activity in 1925 and had already experienced a moderate decline at the beginning of the depression that culminated in 1933 in the smallest sales in any year since slate production was an infant industry. Subsequent recovery was strong at first but is still far below the 1925 level.

Figure 3 presents the same history as figure 2, except that quantities rather than values are used. Roofing granules and flour are most important upon a tonnage basis. Mill stock has a relatively high unit value, and the quantities involved are not great. It is noteworthy that for the year of peak production the value of mill stock was much greater than that of granules and flour, but upon a quantity basis mill-stock sales comprised scarcely one-tenth the tonnage of granules and flour.

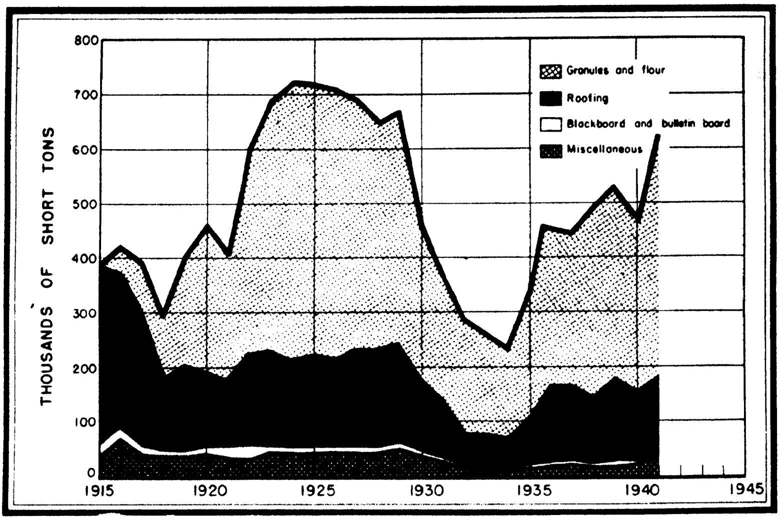

FIGURE 3.—Quantity of slate sold in the United States, 1915–41, by uses.

Granules and flour.—Slate granules are used extensively in surfacing prepared roofing; and slate flour is employed as a filler in paints, road asphalt-surface mixtures, roofing mastic, oilcloth, linoleum, and various other products. The following table shows sales of granules and flour by producers from 1937 to 1941.

Crushed slate (granules and flour) sold by producers in the United States, 1937–41

Year	Granules		Flour		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1937	193,950	$1,309,549	83,060	$268,465	277,010	$1,578,014
1938	258,930	2,220,306	90,070	269,656	349,000	2,489,962
1939	265,830	2,312,177	85,950	268,912	351,780	2,581,089
1940	230,440	2,009,151	88,560	292,750	319,000	2,301,901
1941	323,740	2,708,246	113,930	397,554	437,670	3,105,800

PRICES

The average price of roofing slate f. o. b. quarry or mill, as reported to the Bureau of Mines, increased $1.37 a square in 1941 compared with 1940. In Pennsylvania it increased $1.65, in the Vermont-New York area $1.04, and in Virginia 74 cents a square.

The price of mill stock increased from 30 cents a square foot in 1940 to an average of 33 cents in 1941. Average values of electrical, struc-

tural and sanitary slate, grave vaults and covers, and blackboards and bulletin boards increased moderately, whereas slate for billiard-table tops declined 3 cents a square foot. The average price of roofing granules and flour declined 12 cents a ton from 1940.

Price history.—Figure 4 shows the trend in slate prices compared with building materials in general over a 27-year period. Slate prices were lower than those of building materials in general from 1915 to 1920, but from that time until 1932 prices of both roofing and mill stock were well above the average of all building materials. Since 1932 slate prices have varied only moderately from the general average.

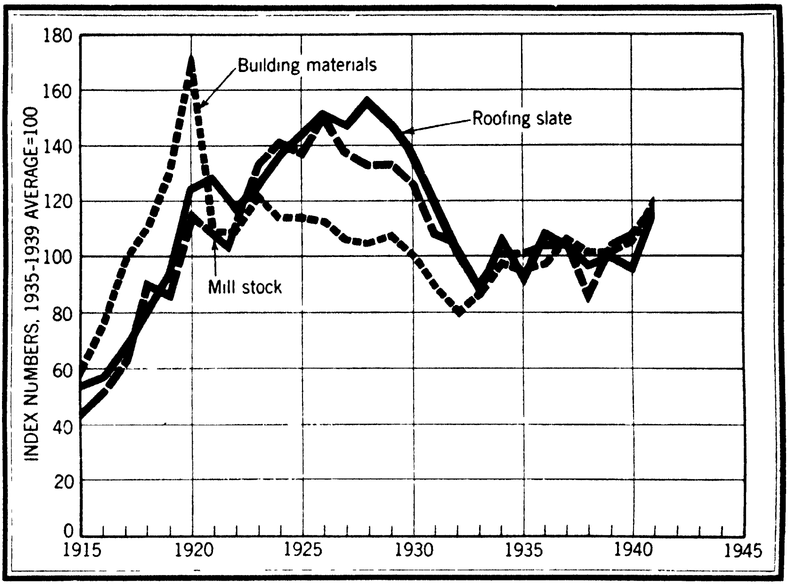

FIGURE 4.—Prices of slate compared with wholesale prices of building materials in general, 1915–41. Wholesale prices are from Bureau of Labor Statistics.

REVIEW BY STATES AND DISTRICTS

The following table gives sales of slate in 1941, by States and uses.

Slate sold by producers in the United States in 1941, by States and uses

State	Operators	Roofing		Mill stock		Other uses [1] (value)	Total value
		Squares (100 square feet)	Value	Square feet	Value		
Arkansas	2					(2)	(2)
California	1					$53,765	$53,765

[2] Included under "Undistributed."
[3] Small amount of mill stock from New York in 1941 and from Vermont in 1940 included under "Other uses."
[4] For details of production in Pennsylvania, see following table.
[5] Includes output of States entered as "(2)" above.

Maine.—Sales of electrical slate—principal product of the Maine quarries—continued to climb in 1941, as shown by a 54-percent increase in total value of slate products sold compared with 1940, which, in turn, followed a 33-percent increase in 1940 from 1939. The growing demand for electrical slate accords with the great increase in electric-power production, which advanced from about 3 to 3½ billion kilowatt-hours from January to December 1941. Roofing slate, which is of minor importance in Maine, made a moderate gain.

New York-Vermont.—The number of squares of roofing slate sold in the New York-Vermont area in 1941 was 4 percent lower than in 1940, following an 18-percent decline in 1940 from 1939; unit prices were, however, so much higher in 1941 that the value of sales gained 10 percent. Mill-stock sales in this area receded 10 percent in quantity but gained 1 percent in value; and the value of other products, chiefly granules and flour, increased 39 percent. The value of all slate products sold in Vermont in 1941 was 24 percent higher and in New York 43 percent higher than in 1940. These substantial gains were, however, confined almost entirely to products other than roofing and mill stock.

Peach Bottom district.—Blue-black slate has been quarried for more than 200 years on the Maryland-Pennsylvania border near Delta, Pa. Roofing slate is now produced only on the Pennsylvania side of the line, but granules and slate flour are manufactured in both States.

Lehigh district.—The most productive slate area in the United States is in Lehigh and Northampton Counties, Pa. All kinds of slate products are manufactured in this district. As separate figures cannot be shown for York County, Pa., it is included with Northampton County in the accompanying table for Pennsylvania.

The value of total sales of slate products in the district was 33 percent higher in 1941 than in 1940. Sales of roofing slate increased 15 percent in quantity and 44 percent in value. The following mill-stock products showed gains in both quantity and value in 1941: Electrical

Slate sold by producers in Pennsylvania in 1941, by counties and uses

County	Operators	Roofing slate		Mill stock					
		Squares (100 square feet)	Value	Electrical		Structural and sanitary		Vaults and covers	
				Square feet	Value	Square feet	Value	Square feet	Value
Lehigh	8	17,590	$108,120	54,310	$25,217	6,740	$2,337	(1)	(1)
Northampton and York [2]	17	231,390	1,967,370	24,950	10,279	631,940	204,544	[1] 246,700	[1] $59,659
Total 1941	25	248,980	2,075,490	79,260	35,496	638,680	206,881	246,700	59,659
1940	27	216,020	1,444,696	48,440	22,110	677,940	204,716	251,070	57,604

County	Mill stock—Continued						Other uses (value)	Total value
	Blackboards and bulletin boards		Billiard-table tops		School slates			
	Square feet	Value	Square feet	Value	Square feet	Value		
Lehigh	177,830	$35,205			522,830	$12,267	(3)	[1 3] $183,146
Northampton and York [2]	680,160	163,261	238,850	$69,674			[3] $806,415	[1 3] 3,281,202
Total: 1941	857,990	198,466	238,850	69,674	522,830	12,267	806,415	3,464,348
1940	1,023,250	229,687	243,700	80,364	413,860	8,637	561,987	2,609,801

[2] York County produced roofing slate, granules, and flour only
[3] Small amount of flagging produced in Lehigh County included under Northampton and York Counties.

slate (64 percent in quantity and 61 percent in value) and school slates (26 percent in quantity and 42 percent in value). Blackboard and bulletin-board sales declined 16 percent in quantity and 14 percent in value. There were only small changes in sales of structural and sanitary slate, vaults and covers, and billiard-table tops. Other products, chiefly granules and flour, gained 43 percent in value compared with 1940.

Virginia.—Sales of blue-black roofing slate—principal product of the Buckingham County area—increased moderately in 1941 compared with 1940. The granule industry of Esmont, Albemarle County, and New Canton, Buckingham County, was active.

Other districts.—A small quantity of granules was produced in Arkansas at Caddo Gap, Montgomery County, and near Mena, Polk County. Larger quantities of granules and flour than in 1940 were produced near Placerville, Eldorado County, Calif., and Bartow County, Ga., near Fair Mount.

Map of slate areas.—The accompanying map, figure 5, shows the location of slate mines and prospects in the United States. The prospects indicated are confined to those that have actually produced slate in substantial quantities some time during their history. As slate is a product of extreme regional metamorphism, active operations are

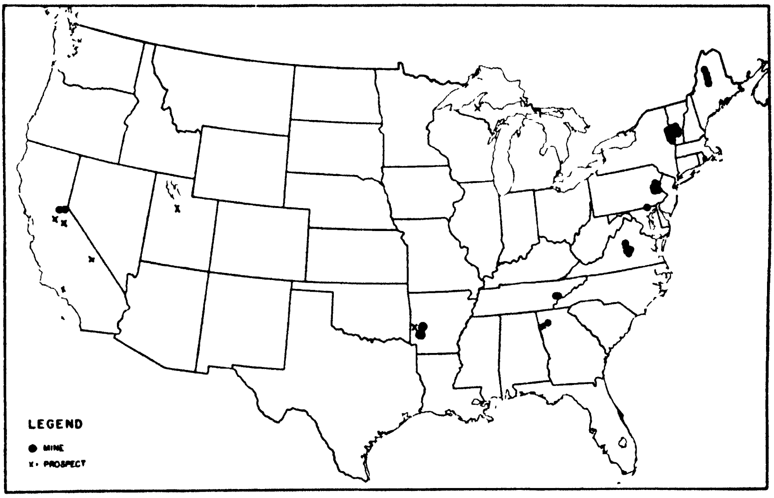

FIGURE 5.—Location of slate mines and prospects in the United States.

confined chiefly to the highly altered rocks of the eastern Appalachian belt extending from Maine to Georgia. No other slate areas have proved adequate to support sustained production, except on a small scale. Very little slate other than granules and flagging has been produced west of the Appalachian area or south of Virginia for many years.

NEW DEVELOPMENTS

The slate industry of the United States faces an unusual opportunity for winning new markets during the present emergency. The war program has created an unparalleled and ever-increasing demand for metals of all kinds; for lumber; and for the essentials of prepared roofing, namely, rag or wood-pulp felts and asphalt. On the other

hand, slate has few direct military uses and therefore may be utilized freely as roofing and for many interior structural applications, unhampered by priorities. Its wider use would thus release larger quantities of the more essential commodities for war needs. Furthermore, it has been found in England that slate roofs offer superior bombing protection and are particularly effective in reducing the spread of fires caused by incendiary bombs. Slate is used extensively in rebuilding bomb-devastated areas in Great Britain.

The field for expansion of the United States slate industry is very broad. Although slate roofs are waterproof, attractive, and unusually enduring, they cover only 1 percent or less of our homes. The North Wales slate industry alone employs more than 8,000 workers in normal times; the entire United States slate (excluding granules) industry employed less than 1,000 wage earners in 1939, according to the Bureau of the Census.

FOREIGN TRADE [1]

Imports.—Imports of slate into the United States are very small. Their value for the past 5 years is indicated in the following table. Owing to war-time restrictions, data for 1941 have been released for only the first 9 months.

Slate imported for consumption in the United States, 1937–41, by countries

Country	1937	1938	1939	1940	1941 (Jan.-Sept.)
Canada	$826	$543	$570		$71
China		3	26	$21	45
Czechoslovakia	990	1,037			
France		895			
Germany	17

	152,151	157,597	177,790	196,694

[1] Figures collected by Bureau of Mines from shippers of products named.
[2] Includes slate used for pencils and educational toys
[3] Includes slate for floors and walkways.

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

SAND AND GRAVEL

By OLIVER BOWLES AND G. E. TUCKER

SUMMARY OUTLINE

SUMMARY

Production of sand and gravel totaled 288,715,000 short tons in 1941 and surpassed all previous records. The quantity sold or used was 21 percent and the total value 33 percent higher than in 1940. The substantial gains were confined to commercial operations; Government-and-contractor [1] production was virtually unchanged. The average value per ton of all material handled was 51 cents in 1941 at point of production compared with 46 cents in 1940 and 47 cents in 1939. The quantity and value of total production over a period of years are indicated in figure 1.

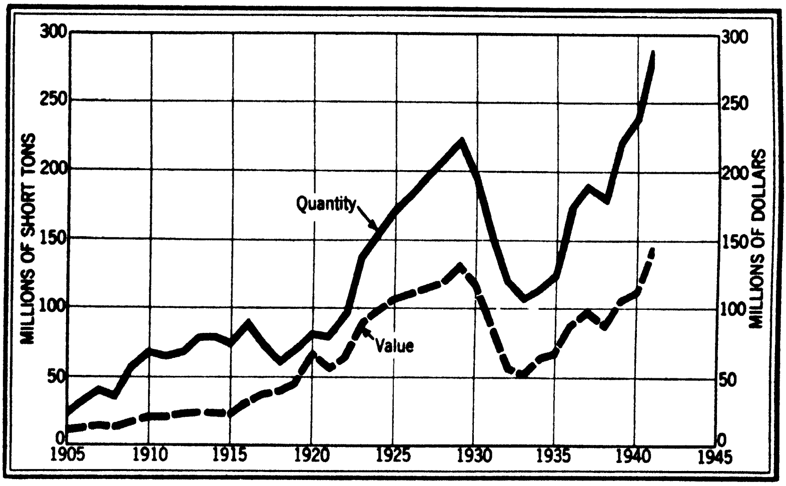

FIGURE 1.—Total production of sand and gravel in the United States, 1905–41.

As the major uses of sand and gravel are for concrete aggregate and road stone, a substantial increase in sales was to be expected in view of the fact that the value of all construction in 1941 was more than twice the 1935–39 average, and awards on contracts for concrete pavement (in thousands of square yards) were 36 percent greater in 1941 than in 1940.

Sales of industrial sands also made large gains. Molding and fire or furnace sands naturally registered substantial gains because of unusual

[1] Prior to 1939 classified as "noncommercial"; details of change in designation given in Minerals Yearbook, 1940, Review of 1939, p. 1214.

activity in foundry work in connection with the program of military preparedness.

Salient statistics on sand and gravel for 1940 and 1941 are summarized in the following table.

Sand and gravel sold or used by producers in the United States, 1940–41, by commercial and Government-and-contractor operations and by uses

	1940			1941			Percent of change in—

[1] Includes blast sand as follows—1940. 256,104 tons valued at $597,198, 1941 371,049 tons, $912,626.
[2] Includes ballast sand produced by railroads for their own use as follows—1940. 57,741 tons valued at $9,506; 1941. 37,911 tons, $5,676.
[3] Includes some sand used by railroads for fills and similar purposes as follows—1940. 207,941 tons valued at $44,064; 1941· 351,537 tons, $36,737.
[4] Includes ballast gravel produced by railroads for their own use as follows—1940· 4,913,809 tons valued at $914,990; 1941: 7,536,591 tons, $1,506,121.
[5] Includes some gravel used by railroads for fills and similar purposes as follows—1940: 793,709 tons valued at $133,405, 1941. 1,157,557 tons, $128,993
[6] Approximate figures for States, counties, municipalities, and other Government agencies directly or under lease

PRODUCTION

As stocks of sand and gravel in the hands of producers are seldom large and as they do not vary greatly from year to year, the quantities of materials sold or used are virtually equivalent to production. Throughout this report sales and production are used interchangeably. The following table segregates sand and gravel and summarizes total production of each over a 5-year period.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States, 1937–41

Year	Sand		Gravel (including railroad ballast)		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1937	63,385,071	$40,412,497	126,275,352	$57,060,500	189,660,423	$97,472,997
1938	57,113,828	33,935,725	124,206,405	51,987,122	181,320,233	85,922,847
1939	72,542,000	41,608,000	153,466,000	64,458,000	226,008,000	106,066,000
1940	78,674,000	45,332,000	159,634,000	65,356,000	238,308,000	110,688,000
1941	103,835,000	62,152,000	184,880,000	85,055,000	288,715,000	147,207,000

Details on production in 1941, by States and uses, are presented in the following tables. California, New York, Illinois, Ohio, Michigan, and Pennsylvania, in the order named, were the leading States in commercial output in 1941; each produced over 10 million tons.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States in 1941, by States

[1] Included under "Undistributed."
[2] Includes, in addition to items entered as "1" sand and gravel produced on W. P. A. projects.
[3] Includes 371,049 tons of blast sand valued at $912,626.
[4] Includes 37,911 tons of ballast sand valued at $5,676, produced by railroads for their own use.
[5] Includes 351,537 tons of sand valued at $36,737, used by railroads for fills and similar purposes.
[6] Includes 7,536,591 tons of ballast gravel valued at $1,506,12?, produced by railroads for their own use.
[7] Includes 1,157,557 tons of gravel valued at $128,993, used by railroads for fills and similar purposes.

Location of plants.—Figure 2 shows the location of all pits reported to the Bureau of Mines as producing sand or gravel, or both, used in any kind of construction in 1940. Each dot represents an active pit, regardless of the volume of material produced. Inasmuch as 1940 was a fairly active year in the building trades and new pits can be opened without difficulty, the map may be regarded as a reasonably accurate index of commercial sources of supply. Sand and gravel pits are numerous and widely scattered. They are abundant in the glacial deposits of the northeastern quarter of the United States but are scattered south of the Ohio and Missouri Rivers, which mark the southern limits of the terminal moraines. Many deposits occur on the Pacific coastal plain. River beds and their banks are important sources of supply. The concentration of pits along the Mississippi and Ohio Rivers is noteworthy. The Arkansas, Missouri, and Willamette Rivers are not shown on the map, although their courses may be traced by the pits along their channels.

The extent of reserves of sand and gravel can be judged only in part from this map, for many large undeveloped deposits are situated in sparsely settled territory. On the other hand, the large number and close proximity of pits in the populous industrial areas of the Northeastern, Middle Western, and Pacific Coast States indicate intensive development of sand and gravel deposits, and not necessarily a more abundant supply.

Government-and-contractor production.—The quantity of sand and gravel reported by State government agencies for 1941 increased 7 percent over that reported for 1940 and represented 37 percent of the total Government-and-contractor output during 1941; of this quantity, 54 percent was produced by contractors. Counties reported 21 percent and municipalities 1 percent of the production. The remaining 41 percent was produced largely by Federal agencies, including the Forest Service, National Park Service, Bureau of Public Roads, Bureau of Reclamation, Soil Conservation Service, United States Engineer Office, and Work Projects Administration.

Average values of the materials were higher than in 1940, except the output by or for counties. Other details are shown in the following tables.

Sand and gravel sold or used by Government-and-contractor producers in the United States, 1937–41, by uses

Municipalities	2,232,786	.33	2,093,000	.26	1,923,000	.28	1,637,000	.29
Other agencies	11,000,205	.34	53,164,000	.38	46,787,000	.38	43,573,000	.40
	75,560,447	.28	107,615,000	.32	107,052,000	.30	107,159,000	.30

METHOD OF TRANSPORTATION

Sand and gravel are conveyed from pit to destination by truck, railway, or waterway. In 1934, 57.4 percent of the total shipment was by rail; a steady decline in rail shipments had been noted from that year until the recovery recorded in 1941.

Sand and gravel sold or used by commercial producers in the United States, 1940–41, by methods of transportation [1]

Method of transportation	1940		1941	
	Short tons	Percent of total reported	Short tons	Percent of total reported
Truck	54,063,146	45.8	74,452,542	44.9
Rail	45,254,984	38.4	69,225,395	41.7
Waterway	18,600,060	15.8	22,201,899	13.4
Total reported	117,918,190	100.0	165,879,836	100.0
Percent of total commercial production covered		89.8		91.0

[1] For practical purposes the entire output of Government-and-contractor operations commonly is moved by truck. Including Government-and-contractor production, sand and gravel moved as follows—1940: Truck 72 percent, rail 20 percent, and waterway 8 percent; 1941: Truck 67 percent, rail 25 percent, and waterway 8 percent.

DEGREE OF PREPARATION

Specifications for sand and gravel are becoming increasingly rigid. Although in many regions nature has sorted its materials remarkably well, relatively few deposits supply products that will satisfy market requirements without screening or washing. In 1941, 88 percent of all commercial production was processed in some way, and the remainder was sold as bank-run material. On the other hand, only 21 percent of the Government-and-contractor production was processed. This accounts largely for the low average value per ton of the Government-and-contractor output compared with commercial production.

Sand and gravel (prepared or unprepared) sold or used by producers in the United States, 1940–41, by commercial and Government-and-contractor operations

	1940			1941		
	Quantity		Average value per ton	Quantity		Average value per ton
	Short tons	Percent		Short tons	Percent	
Commercial operations:						
Prepared	115,425,213	88	$0.63	159,784,239	88	$0.67

	107,052,000	100	.30	107,159,000	100	.30
Grand total	238,308,000	----------	.46	288,715,000	----------	.51

SIZE OF PLANTS

More than half of the commercial sand and gravel plants of the United States are in a size group that produces less than 25,000 tons annually, but this large group contributed only 8.1 percent of the total production in 1940. Medium-size plants furnish the bulk of the output. In 1940, 61.5 percent of the total came from plants having an annual production between 25,000 and 300,000 tons. Details of output, by size groups, for 1939 and 1940 are given in the following table.

Comparison of number and output of commercial sand and gravel plants in the United States, 1939–40, by size groups [1]

Size group in short tons	1939				1940			
	Plants [2]		Production		Plants [2]		Production

1,000,000 and over	6	.3	7,666,000	6.8	5	.2	6,855,000	5.5
	2,081	100.0	112,553,000	100.0	2,239	100.0	125,283,000	100.0

[1] Plants operated by or for States, counties, and municipalities are not included; also not included are approximately 194 railroad plants with an output of 5,840,000 tons of sand and gravel in 1939 and 187 plants with an output of 5,973,000 tons in 1940.
[2] May include a few companies operating more than 1 plant but not submitting separate reports for individual plants.

PRINCIPAL TRENDS

Sand and gravel for construction.—Markets for sand and gravel depend primarily on the construction industries. Figure 3 shows the correlation between highway construction and sales of gravel, as well as the relation of sand output to construction activity in general. Construction of numerous military establishments during 1941 created a strong market for building sand and gravel, which was supplemented by the demands of active private construction and extensive highway work. The magnitude of the 1942 market is problematical because highway building, except that of military importance, has been curtailed drastically, and the program of private building has been reduced greatly. Direct military construction and all types of building that are or will be authorized because of their

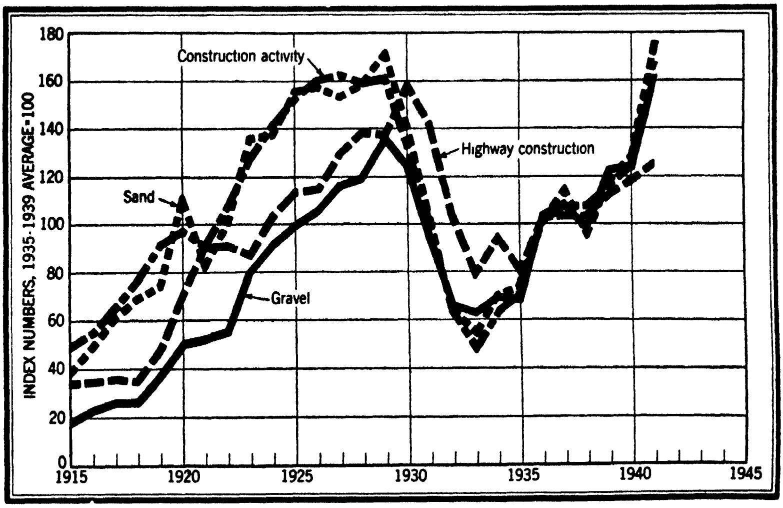

FIGURE 3.—Comparison of production of sand and gravel with highway construction (including maintenance) and construction activity (including maintenance and work relief) in the United States, 1915–41. Data on highway construction and construction activity from Bureau of Foreign and Domestic Commerce.

indirect promotion of the military program will continue at a high level and may counteract the decline in nonmilitary construction.

Industrial sands.—Sand has important uses in manufacturing industries, and the volume of sales fluctuates in consonance with industrial activity. With foundries working at virtually 100 percent of capacity, the demand for molding and fire or furnace sand has been unparalleled. The glass industry has been active because of the movement to substitute glass for metals and the high level of carloadings is indicated by a growing demand for engine sand. Increased industrial activity in various fields has promoted a wider use of grinding and polishing sand. Figure 4 shows graphically the history of production of industrial sands since 1916.

As indicated in figure 5, sales of molding sand follow in general the trend of industrial production. They also show marked correlation with the number of automobiles manufactured during recent years, but such correlation will cease in 1942.

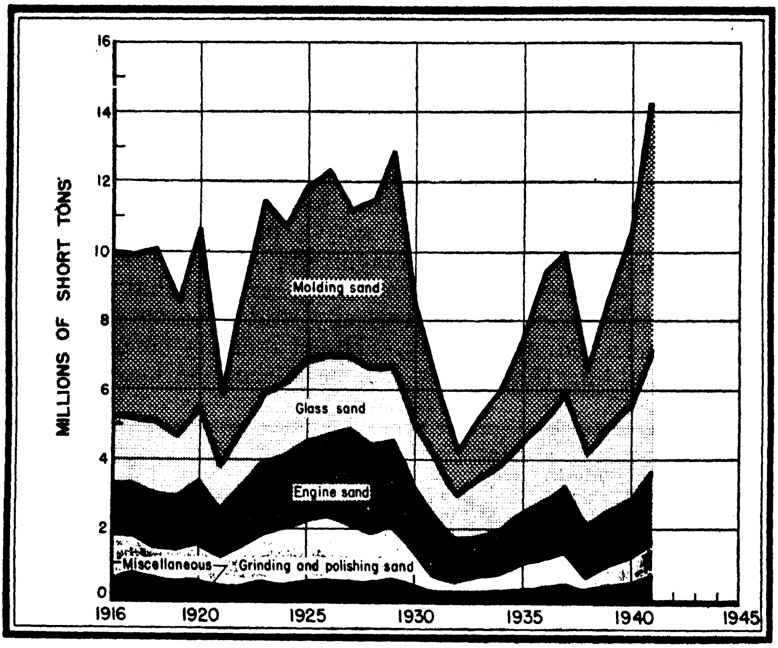

FIGURE 4.—Production of industrial sands in the United States, 1916–41.

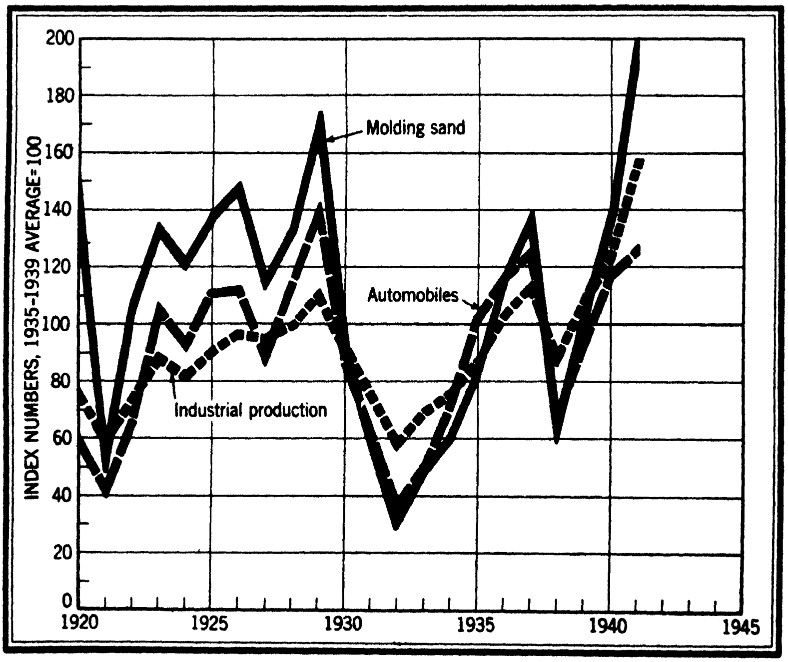

FIGURE 5.—Trends in sales of molding sand compared with automobiles manufactured and industrial production, 1920–41. Statistics on automobiles from Bureau of the Census. Index of industrial production from Federal Reserve Board.

EMPLOYMENT AND PRODUCTIVITY [2]

Data on employment and output per man in the sand and gravel industry have been recorded since 1933.[3] The figures for 1940 that follow are based upon operations reporting more than three-fourths of the total commercial production. Data for 1941 are not yet available.

The number of men employed was 6 percent higher in 1940 than in 1939, the average number of days employed increased 1 percent, and the average length of shift was virtually the same as in 1939. The average productivity was 3.3 short tons per man per hour, which is the same as the average for the 4 years 1936–39.

Employment in the commercial sand and gravel industry, sand and gravel produced at plants included in the study, and average output per man in the United States, 1935–40 [1]

Year	Employment					Production			Percent of commercial industry represented
	Average number of men	Time employed				Commercial sand and gravel (short tons)	Average per man (short tons)		
		Average number of days	Total man-shifts	Man-hours					
				Average per man per day	Total		Per shift	Per hour	
1935	11,926	197	2,351,453	8.3	19,578,368	60,826,691	25.9	3.1	75.4
1936	16,127	207	3,332,532	8.6	28,672,615	95,219,468	28.6	3.3	83.8
1937	16,062	215	3,458,994	8.6	29,754,746	97,113,001	28.1	3.3	81.8

1940	16,595	217	3,596,886	8.4	30,263,744	101,143,305	28.1	3.3	77.1

[1] Excludes plants operated by or directly for States, counties, municipalities, and other Government agencies.

Productivity data by regions for 1940 are summarized in the accompanying table. The most notable changes to be observed in comparison with 1939 are the smaller output per man per hour in New York and in the Wyoming-Colorado-New Mexico-Utah-Arizona area and the increased productivity in the South Carolina-Georgia-Alabama-Florida-Mississippi area. The highest productivity (5.4 tons per man per hour) was attained in the Michigan-Wisconsin area.

[2] Statistics on employment and productivity compiled by Elva T. Shuey from records of the employment statistics section, Bureau of Mines.

[3] See Minerals Yearbook 1935, pp. 941–943; 1936, pp. 843–845; 1940, Review of 1939, pp. 1218–1221; and Review of 1940, pp 1191–1193

[1] Excludes plants operated by or directly for States, counties, municipalities, and other Government agencies.

PRICES

Prices for commercial sand and gravel were, in general, higher in 1941 than in 1940. The largest gains were in molding sand, which increased from $1.05 to $1.16 a ton, and in grinding and polishing sand, which increased from $1.07 to $1.39 a ton. The prices of filter sand and fire or furnace sand declined. The average price of total commercial gravel increased 5 cents a ton. Building gravel increased from 65 to 71 cents a ton and paving gravel from 59 to 64 cents. Railroad-ballast prices remained unchanged.

The average price of total Government-and-contractor sand and gravel remained unchanged. Building sand declined from 40 to 31 cents, but paving sand increased from 29 to 31 cents a ton. The same trends were apparent in gravel; that used for building declined, whereas that for paving rose.

NEW DEVELOPMENTS

New aggregate problems arise at each great dam built in the Far West. At Boulder Dam the problem was quantity production and storage; at Grand Coulee it was disposal of an excess of fine sand. At Shasta Dam just the reverse condition exists from that at Grand Coulee, because there is a dearth of fine sand. Ball mills and rod mills had to be installed to reduce the minus-3/16-inch sand to three finer sizes, namely, 4- to 28-, 28- to 60-, and 60- to 100-mesh. The various sizes of gravel and sand are blended in exact proportions as required. Gold is recovered as a byproduct of the sand.

The plant supplying the aggregate, situated near Redding, Calif., has a 1,200-ton-per-hour washing and screening plant. A unique feature is a 10-mile belt-conveyor system to carry aggregates to the dams. The belts travel 550 feet a minute, and the haulage cost is said to be only half as much as rail transportation.

A Pennsylvania gravel company reduces surplus gravel to sand sizes by means of a recently developed type of impact crusher. The size of the gravel and boulders is reduced by hurling them at high velocity against breaker plates. The method is said to be efficient. The impact crusher is employed at some plants simply to eliminate soft stone.

Research is being directed toward obtaining improved adhesion between aggregates and bituminous bonding materials, thus increasing the durability of road surfaces.

The Los Angeles abrasive-testing machine has been adapted to test extremely small and exceptionally large aggregates, as well as intermediate grades.

The Bureau of Mines has developed refinements in the purification of glass sands involving application of froth flotation, agglomeration, and attrition scrubbing to remove impurities.

The more-refined methods of treating sand include acid leaching to reduce the iron content to as low as 0.01 percent, fine grinding in air-swept tube mills controlled by "electric ears," and the use of bag-type dust collectors, not only to protect workers from pulmonary diseases but also to recover considerable quantities of extremely fine grained materials that are salable for use in soaps, scouring powders, and other abrasive products.

FOREIGN TRADE [4]

Because of intensified warfare and difficulties of transportation, imports of sand and gravel during 1941 were very small and were obtained chiefly from Canada. No glass sand was imported.

Exports of sand and gravel were not recorded separately in 1940 and 1941.

[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Sand and gravel imported for consumption in the United States, 1940–41, by classes and countries

BLAST-FURNACE SLAG

Continuing the policy inaugurated in 1938, the National Slag Association conducted a canvass of 30 companies (64 plants) that prepare blast-furnace slag for commercial use. The total output for 1941 was 14,678,266 short tons valued at $11,064,102. Of this total, 84 percent was air-cooled and screened, 5 percent air-cooled and unscreened, and the remainder granulated. Sales of screened and air-cooled slag were 52 percent greater in 1941 than in 1940, and the average value per ton was 2 cents lower.

About 73 percent of all slag processed is treated in Ohio, Alabama, and Pennsylvania; however, it is marketed in all States east of the Mississippi River except several New England States too far removed from sources of supply to permit economic utilization.

Air-cooled slag is used principally in the construction and maintenance of highways, as well as in airport runways, parking lots, and building construction and as railway ballast. It is used quite extensively as roofing aggregate and in the manufacture of mineral wool. Granulated slag is used primarily as fill material and as an ingredient of

portland cement. Other uses and the quantities involved are shown in the accompanying table.

Particles of metallic iron that escape through the slag notch of the blast furnace are recovered during the screening process by means of a magnetic separator supplemented by hand picking. During 1941, 137,500 tons of metal were thus recovered and returned to the furnaces to augment supplies urgently needed for the war program.

Exclusive of administrative, office, and sales employees, 1,536 men were employed in processing slag in 1941. A production of 4.8 short tons per man-hour was attained.

Shipments of slag, by methods of transportation, were as follows: Railroad, 55 percent; truck, 43 percent; and waterway, 2 percent.

Air-cooled blast-furnace slag sold or used by producers in the United States, 1940–41, by States [1]

GYPSUM

By Forrest T. Moyer

SUMMARY OUTLINE

The total value of all gypsum products sold or used in 1941 was nearly 70 million dollars, or 30 percent higher than in 1940 and far above that of the previous record year, 1925. Outstanding products were portland-cement retarder, lath, wallboard, sheathing board, and miscellaneous tile shapes, for which striking gains were reported over sales during 1940. Crude supply in 1941 is estimated at 6,000,000 short tons and was attained principally by greatly increased production from domestic mines, which more than offset an indicated small decline in imported crude. Kettle and kiln output of calcined gypsum totaled nearly 4 million tons, or 20 percent more than in 1940 Despite increased costs of labor and materials, prices of gypsum products were relatively unchanged from 1940 in most instances; uncalcined products were slightly higher, industrial plasters unchanged, building plasters slightly lower, and prefabricated products slightly higher in price.

The record annual dollar volume of business for the gypsum industry in 1941 resulted principally from the advanced rate of private building activity, to which was added an extensive program of cantonment and emergency housing for the armed forces and for industrial workers. Private building activity was maintained well above that in 1940 until near the close of 1941, when "housing" priorities established September 22 on some structural materials first noticeably began to curtail the volume of construction not essential to the defense program. After declaration of war on Japan, Germany, and Italy in December, the accelerated military program greatly expanded cantonment and defense housing and thus bolstered a faltering market for gypsum products. The present type of residential construction consists largely of small, low-cost units in which speed and ease of erection and salvageability of materials have prime importance. These factors tend toward wider utilization of prefabricated materials, as is shown by the brisk market for gypsum board in contrast to the much less active demand for plasters.

The outstanding feature of the industry in 1941 was the strikingly increased demand for the three types of gypsum board—lath, wallboard, and sheathing—in each of which sales volumes set new annual

records. The net advance in sales of lath over 1940 was nearly 400 million square feet, which was by far the largest annual increment reported for this product. Indicative of its strong competitive position, sales of lath listed in Bureau of Mines Quarterly Gypsum Reports reached a new record quarterly total in the October-December period of 1941, when a volume of one-half billion square feet was exceeded for the first time. Also evident from this record is the apparent extensive substitution of gypsum lath for metal lath, which was placed under priority regulations after September.

Owing to its widespread use in the construction of barracks, consumption of wallboard in 1941 increased markedly over 1940 to a total of 757½ million square feet and greatly exceeded the quantity sold in any other year.

Although gypsum sheathing was relatively unknown and sales were negligible as recently as 1939, its low cost and adaptability for construction of cantonments and other emergency housing were recognized early in the defense program. Sales jumped from 5¼ million square feet in 1939 to 89½ million in 1940, nearly all of which was sold in the October-December period. In 1941, sales totaled 175 million square feet, another spectacular gain in use that indicates the widespread acceptance of this product as a proved and satisfactory material.

[2] Excludes byproduct gypsum
[3] Figures cover January to September, inclusive
[4] Data not available.
[5] Made from domestic, imported, and byproduct crude gypsum.

Despite greatly increased shipping difficulties due to the war, imports of crude gypsum in the first 9 months of 1941 totaled 868,234 short tons, a decline of only 15 percent from the record tonnage imported during the similar period of 1940. Tidewater calcining plants along the Atlantic coast appeared to have supplies of crude adequate for normal operations in 1941. However, about the middle of the year

some crude reportedly was shipped from the Buffalo region to a calcining plant in the metropolitan New York area via the New York Barge Canal. If imports are halted completely and calcining capacity is needed, crude gypsum for at least partial operation of some tidewater plants probably could be transported from domestic mines by water. It would be more economical, however, to ship calcined gypsum or the finished products into the eastern market area.

Wage increases during 1941 were reported by operators in California, Iowa, Michigan, Nevada, Oklahoma, and Utah, and labor agreements were effected between operators and unions in several producing localities. Labor difficulties lasting through July and August closed nine gypsum operations (eight plants and one mine) in seven States; at the close of 1941 a final agreement had not been reached, although the case had been referred to the National War Labor Board and work had been resumed in all plants.

Jury trial of the criminal charges of fixing prices on gypsum products, brought by the Department of Justice against five producing companies and eight officials, resulted in a directed verdict of acquittal. Still pending are the criminal actions against three companies for alleged illegal price control of perforated lath and a civil action on seven companies and seven officials for conspiring to restrain trade and control prices in violation of the Sherman Antitrust Act.

The wide and rather regular distribution of domestic mines and plants processing gypsum is shown on the map (fig. 1) of gypsum operations. The New England, Southeastern, and Pacific Northwest States lack domestic sources of crude supplies, but only the Pacific Northwest is without a gypsum-processing plant.

DOMESTIC PRODUCTION

Domestic mines produced 29 percent more crude gypsum in 1941 than in 1940; the output was obtained in 16 States from 60 operations, comprising 28 underground mines, 26 open quarries, and 6 mine-quarry

Crude gypsum mined in the United States, 1939–41, by States

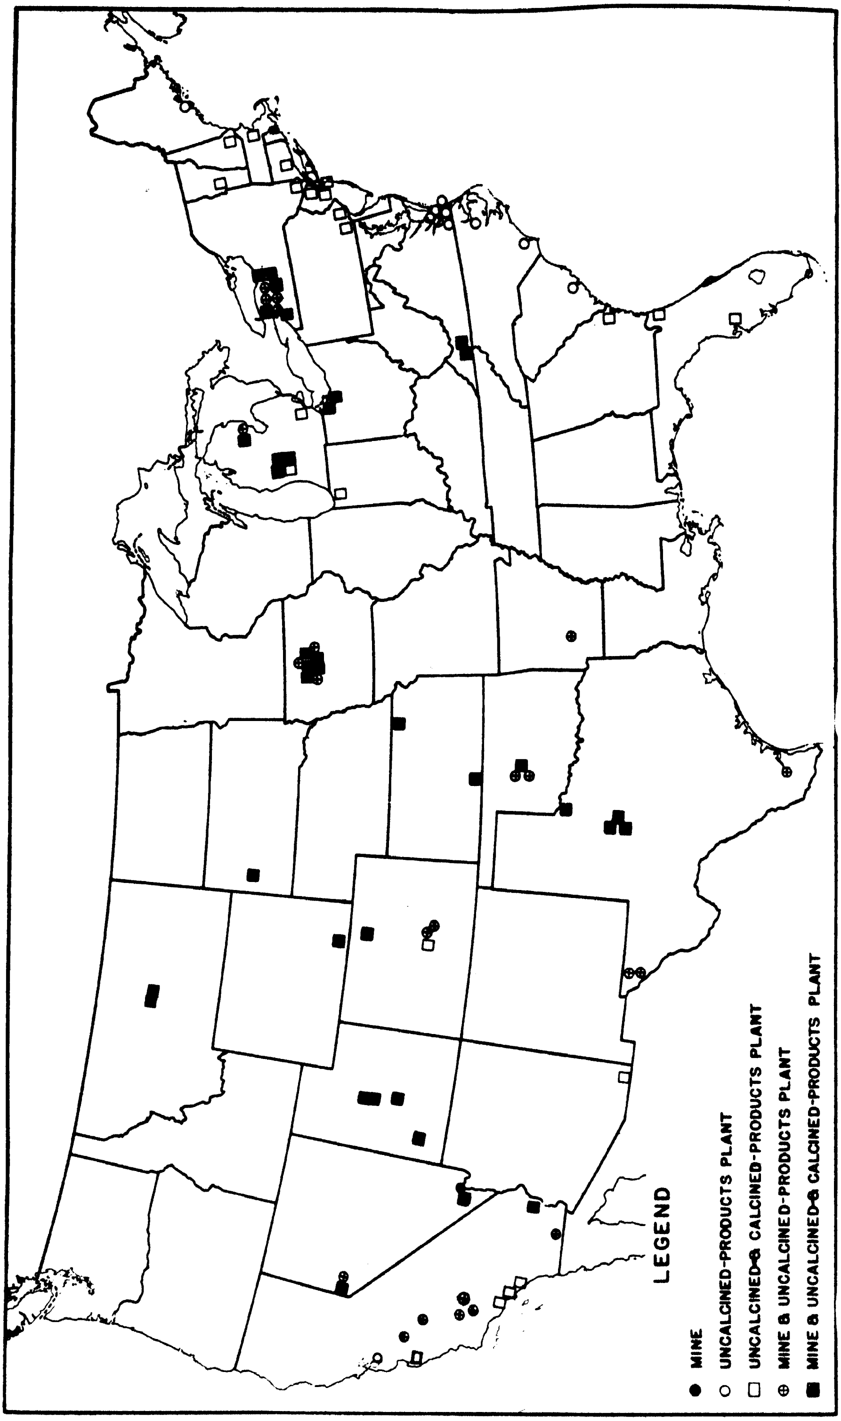

FIGURE 1.—Geographic distribution of gypsum mines and processing plants in the United States.

combinations. Output increased in nearly all the States, with New York, Michigan, Iowa, and Texas (in order of tonnage) continuing as the leading producers.

Average estimated value of run-of-mine gypsum advanced 1 cent to $1.42 per ton in 1941. As reported by the producers, this is essentially a "transfer" value, because run-of-mine material seldom is bought and sold in open market. Data in the preceding table do not include byproduct crude gypsum.

CAPACITIES AND EQUIPMENT OF PROCESSING PLANTS

Calcined gypsum was produced in 25 States by 57 plants—45 processing domestic crude, 11 imported crude, and 1 byproduct crude gypsum. Total kettle and kiln output was 3,980,567 short tons—a net gain of 672,858 tons over 1940. Active calcining equipment included 179 kettles, 13 rotary kilns, 8 beehive kilns, and 4 grinding-calcining kiln-mills. Equipment that was idle throughout 1941 included 10 kettles, 1 rotary kiln, and 1 beehive kiln.

[1] Capacities expressed as output of "first-settle" calcined gypsum suitable for use in common wall or base-coat plasters. Figures do not include data on beehive kilns, see text.
[2] Includes data on active rotary kilns in this district.
[3] Included with data on active kettles in this district.
[4] Includes data on inactive kettles in this district.
[5] Included with active capacity of this district.
[6] Figures refer to grinding-calcining kiln-mills.
[7] Includes data on active grinding-calcining kiln-mills.

The capacities of calcining equipment in plants that were active during all or part of 1941 totaled 30,015 short tons per 24 hours of "first-settle" calcined gypsum suitable for use in common wall or base-coat plasters. The data in the preceding table include the capacity of a new calcining plant in Nevada that did not begin operations until early in 1942 but do not include the capacities of two inactive calcining plants, one in California and the other in Washington. The capacities of beehive kilns are not included, as equipment of this type is adapted only to the manufacture of Keene's cement.

Processors' reports on the average number of operating days a year for each kettle after allowances for repair shut-downs, etc., ranged from 45 to 340 days. However, the largest grouping of kettles was in the range from 251 to 300 days, in which reports on 76 kettles had an arithmetical average of 294 days a year. For rotary kilns, reports on the number of working days a year ranged from 135 to 330 and averaged 252 days. By calculations employing the figures on operating days, active daily capacity of kettles and rotary kilns, and calcined gypsum production it is shown that only 48 percent of the calcining capacity of the country was utilized in 1941.

Plants along the Atlantic seaboard that depend on imported supplies of crude have an aggregate active calcining capacity of 6,917 short tons and a total capacity of 7,031 tons per 24 hours.

Because gypsum board of different type and thickness is made at different speeds on account of drying problems, the total capacities of the manufacturing machines are shown in the accompanying table for each of three standard types and two thicknesses of board. The capacities of a new machine that began operations early in 1942 are included in the data. The aggregate capacity of the 36 active board machines is 13,104,600 square feet of ⅜-inch lath in 24 hours, but when making sheathing their capacity falls to 7,438,280 square feet. Reports on the number of operating days in the year per machine ranged from 217 to 350 and averaged 304 days.

Number and capacities [1] of active gypsum-board machines in the United States in 1941, by standard types of board and by districts

District	Number of machines	Capacity per 24-hour day, in square feet of—				Operating days per machine in year [2]	
		⅜-inch lath	⅜-inch wallboard	½-inch wallboard	½-inch sheathing board	Range [3]	Average [4]
New Hampshire, Massachusetts, eastern New York, New Jersey, and Pennsylvania	6	2,562,000	2,059,000	1,610,000	1,321,000	300–330	311
Western New York	6	2,130,400	1,945,200	1,423,000	1,340,800	300–353	320
Ohio, Michigan, and Indiana	7	2,576,400	2,126,600	1,597,200	1,336,680	231–350	299
Iowa	3	1,280,800	993,800	777,600	696,800	240–320	287

[1] Expressed as square feet per 24 hours upon basis of manufacturing only standard board of specified type during the 24 hours.
[2] Estimated by processor at capacity rate of operation, after allowances for repair shut-downs, etc.
[3] In reports on individual machines
[4] Sum of operating days for each machine divided by number of machines.

From the data in the table, multiplication factors to convert square footages of one board type into an equivalent area of ⅜-inch lath are as follows: For ⅜-inch wallboard, 1.191; for ½-inch wallboard, 1.566; and for ½-inch sheathing, 1.762. Using the foregoing data and assuming that half of the wallboard sales were of ⅜-inch thickness and the remainder of ½-inch thickness, it is calculated that the rate of board manufacture was 81 percent of the total available capacity at the end of 1941. The actual rate of operations was higher, however, as the calculations do not allow for spoilage and breakage and all of the machines were not available throughout the year.

DISTRIBUTION OF SALES BY USES

The pronounced gain in sales of portland-cement retarder over 1940 correlates closely with the increased rate of operations in the portland-

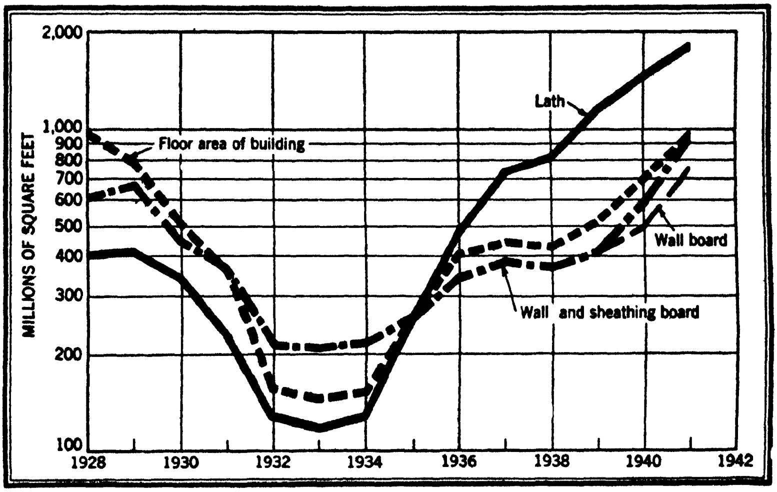

FIGURE 2.—Sales of gypsum lath and wall and sheathing boards compared with F. W. Dodge Corporation figures on floor area of residential and nonresidential building, 1928–41.

cement industry. Although consumption of agricultural gypsum in the Virginia and Carolina peanut area declined to approximately 50,000 short tons in 1941, total consumption in the country, after adjustment for comparability, was about 10 percent higher than in 1940, principally because its use was increased in California on all types of soil for fertilizing potatoes, cotton, alfalfa, and grapevines.

All classes of industrial plasters showed marked sales increases during 1941, and the total tonnage for this group was 23 percent above 1940. The use of gypsum plaster to make molds for metal castings is said to be increasing steadily under the stimulus of the war program.

Sales volumes of all the principal classes of building plasters were higher than in 1940, except for the group of miscellaneous plasters (patching, painter's, etc.) in which sales dropped 13 percent.

Notable features shown in figure 2 are the marked expansion in use of gypsum lath since 1933 and the effects of the defense and war programs upon consumption of the three types of gypsum board since 1940. Sales of sheathing before 1939 are said to be negligible and

are included with those of wallboard The semilog or ratio scale used in figure 2 shows fluctuations in the annual physical volume of sales and floor area of building and also permits ready comparison of the rates of increase or decrease.

Gypsum products (made from domestic, imported, and byproduct crude gypsum) sold or used in the United States, 1940–41, by uses

Use	1940			1941

[1] Not comparable; see text.
[2] Includes uncalcined gypsum sold for use as filler and rock dust, in paint manufacturing, and for minor purposes.
[3] Includes statuary, industrial casting and molding plasters, dead-burned filler, and miscellaneous sales.
[4] Includes joint filler, patching and painter's plaster, and unclassified building plasters.
[5] 1940: 1,450,069 M square feet; 1941: 1,843,048 M square feet.
[6] Average value per M square feet.
[7] Percent of change in square footage.
[8] 1940: 491,291 M square feet; 1941: 757,588 M square feet.
[9] 1940: 89,631 M square feet; 1941: 175,496 M square feet.
[10] Includes partition, roof, floor, soffit, shoe, and all other gypsum tiles and planks—1940: 30,026 M square feet, 1941: 34,877 M square feet.
[11] Average value per M square feet of partition tile only.

Although over-all consumption of gypsum tiles increased markedly in 1941, the gain was due entirely to greatly increased sales of miscellaneous tiles (roof, floor, shoe, etc.) and plank in which square footages sold were more than two and a half times those in 1940. In contrast, sales of partition tiles fell approximately one-fifth below the square footages sold in 1940.

PRICES

Prices of gypsum products, as indicated by the average unit values, f. o. b. plant, showed no general trend in 1941 but remained at essentially the same levels as in 1940. The only significant change was the 13-percent decline noted for the average value of partition tiles. In 1941, the unit value of agricultural gypsum comparable with the 1940 value was $6.01 a ton, a 10-percent gain caused largely by price increases in the Southeastern States necessary to cover the higher transportation costs in obtaining crude supplies from Canada.

RECENT DEVELOPMENTS

Research and technical work in the gypsum industry in 1941 was directed toward the enlarging of capacity to produce gypsum board and the development of products to fit industrial, farming, and other nonbuilding uses. Further refinements were made in the high-strength gypsum cement used for oil-well drilling and in a new molding plaster used in place of sand molds in metal casting work. One company established experimental farms to promote uses of its products.

Satisfactory alkali resistance in exterior concrete and brick paints of the conventional oil types is said to be obtained [1] when 15 to 20 percent of the pigment is gypsum, either as plaster of paris or as terra alba.

Research [2] on calcium sulfate showed the high-temperature form to be unstable and did not confirm the existence of basic sulfates of calcium.

Gypsum or anhydrite in place of salt cake in the kraft-paper industry [3] continues to be a practical substitution in mills where gypsum supplies can be delivered for less than $5 and salt cake for more than $17.40 a ton.

FOREIGN TRADE [4]

Imports and exports of crude gypsum and gypsum products in 1941 are available for publication for the first 9 months only; later data are to be confidential for the war period.

Imports.—Crude gypsum brought to processing plants on tidewater along the Atlantic coast comprises practically all of the import trade in gypsum. During the first 9 months of 1941 crude imports

[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

were 15 percent below the record tonnage that entered the country during the same period of 1940. It is noteworthy, however, that the 9-month volume in 1941 was approximately the same as the 12-month totals in 1937 and 1938. Importations of gypsum products and manufactures virtually ceased in 1941, and 9-month values reported for these classifications aggregated only $42,753, which represents a monthly rate 56 percent lower than in 1940.

Gypsum and gypsum products imported for consumption in the United States, 1937–41

Year	Crude (including anhydrite)		Ground		Calcined		Keene's cement		Alabaster manufactures [1]	Other manufactures, n. e. s.	Total value

[1] Includes imports of jet manufactures, which are reported to be negligible.
[2] January to September, inclusive.

Crude gypsum (including anhydrite) imported for consumption in the United States, 1939–41, by countries

Country	1939		1940		1941 (Jan.-Sept.)	
	Short tons	Value	Short tons	Value	Short tons	Value
Canada	1,243,390	$1,112,967	1,368,194	$1,260,076	865,965	$797,213
China	(1)	18			1	15
Hong Kong					(1)	5
Italy	116	2,942	184	4,495		
Mexico	58,955	53,341	32,134	29,056		
United Kingdom	5,617	4,849	4,698	6,823	2,268	4,063
	1,308,078	1,174,117	1,405,210	1,300,450	868,234	801,296

[1] Less than 1 ton.

Tidewater quarries in New Brunswick and Nova Scotia, Canada, supplied nearly all the crude imported during the first 9 months of 1941. Imports into southern California from San Marcos Island, Baja California, Mexico, ceased in 1940, marking the first break in this raw-material flow that began in 1925 and usually comprised 5 to 10 percent of the total annual crude imports.

Gypsum and gypsum products exported from the United States, 1937–41

Year	Crude, crushed, or ground		Plasterboard and wallboard		Calcined		Other manufactures, n. e. s.	Total value
	Short tons	Value	Square feet	Value	Short tons	Value		
1937	4,777	$26,692	4,360,404	$96,019	2,847	$61,383	$87,048	$271,142
1938	2,844	17,762	3,658,647	88,822	3,833	71,914	104,284	282,782
1939	10,342	41,012	5,258,249	130,073	2,913	69,577	68,791	309,453
1940	5,209	31,564	4,152,452	101,680	2,208	56,419	74,465	264,128
1941 (Jan.-Sept.)	9,019	43,179	7,604,879	159,917	1,986	54,768	53,408	311,272

Export activity increased markedly during 1941, and the monthly rate of total value of materials exported during the first 9 months was 57 percent greater than that in the year 1940; however, exports comprise only a small part of the domestic industry.

WORLD PRODUCTION

The United States doubtless continued to be the leading producer of crude gypsum, although data on production in other countries are fragmentary. Output from Canadian operations was 10 percent higher than in 1940 and set a new record annual tonnage for that country. In other countries that formerly had large production, mining activities undoubtedly were curtailed drastically because of the war.

World production of gypsum, 1937–41, by countries, in metric tons [1]

LIME

By Oliver Bowles and F. D. Gradijan

SUMMARY OUTLINE

SUMMARY

Production of lime attained an all-time high of 6,079,416 short tons in 1941 and exceeded the previous record of 1940 by 24 percent. This marked increase in output was accompanied by an increase of 11 cents a ton in average value for all lime at the point of production.

Sales of agricultural lime increased 5 percent in 1941 compared with 1940, and the average value per ton rose from $5.71 to $6.24. The increase is due in part to activities of Agricultural Adjustment Administration county agents in promoting wider use of liming materials.

Building lime increased 5 percent in volume of sales over 1940, whereas the unit value advanced 3 percent.

Sales of lime for chemical and industrial purposes increased 35 percent over 1940, reflecting the tremendously increased activity in the heavy industries fostered by the war program. The price of chemical and industrial lime held steady, showing an increase of only 0.5 percent over 1940. Sales of refractory lime gained 23 percent in quantity over 1940, accompanied by a sharp upturn in unit value.

Among the major chemical and industrial uses, the most notable gains were in metallurgical lime (37 percent) and in lime used by tanneries (29 percent). For the third consecutive year, the quantity of metallurgical lime consumed in 1941 represented a new all-time high. As in 1940, sales of metallurgical lime increased far more than the increase in steel-ingot output would indicate. It is suggested that this discrepancy may be due in part to the increased use of brown iron ores, which—because of their higher phosphorus content—require larger quantities of flux than the average low-phosphorus ores.

Data on prices show that the steady decline in averages since 1937 has been arrested by an upward trend in all major categories in 1941.

Salient statistics of the lime industry in the United States, 1940–41

	1940			1941

[1] Figures cover January to September, inclusive.

PRODUCTION

As quicklime is a semiperishable product, stocks are never large. Quantities sold or used may therefore be considered equivalent to production.

Production of quicklime was 28 percent greater in 1941 than in 1940, and hydrated-lime production increased 15 percent. Average values were considerably higher. Data on unit values, by individual uses, are indicated in a later section of this chapter. The following table shows production during recent years.

Lime sold or used by producers in the United States, 1937–41

Year	Plants in operation	Short tons [1]	Value [2]	
			Total [1]	Average
1937	314	4,124,165	$30,091,168	$7.30
1938	321	3,346,954	24,137,638	7.21
1939	311	4,254,348	30,049,394	7.06
1940	314	4,886,929	33,956,385	6.95
1941	309	6,079,416	42,941,162	7.06

[1] Includes lime used by producers (captive tonnage) as follows—1937: 270,192 tons valued at $1,388,052; 1938: 168,245 tons, $985,003; 1939: 270,087 tons, $1,454,285; 1940. 339,441 tons, $1,804,017; 1941. 499,062 tons, $2,556,240

[2] Value given represents value of bulk lime f. o. b. at point of shipment and does not include cost of barrel or package.

PRODUCTION BY STATES

Lime was produced in 38 States and 2 Territories during 1941. The leading producers were Ohio, Pennsylvania, Missouri, and West Virginia, which together supplied 60 percent of the total. Ohio alone

contributed 25 percent. The number of plants, production, and value of sales in each State are shown in the following table, insofar as the data can be presented without revealing figures of individual companies.

Lime sold or used by producers in the United States, 1940–41, by States

State	1940			1941		
	Active plants	Short tons	Value	Active plants	Short tons	Value

LOCATION OF PLANTS

The accompanying map (fig. 1) shows the location of active lime plants in the United States that reported to the Bureau of Mines for 1940. The largest demands for building lime, as well as for that used in the chemical and processing industries, are in populous industrial centers. This explains the intensive development of lime plants in Pennsylvania, Maryland, and Ohio. The metropolitan areas of Boston, New York, and Washington, D. C., are notably lacking in lime plants because limestone deposits are not available in these territories. The following nine States had no lime plants reporting activity in 1940: New Hampshire, Delaware, South Carolina, Mississippi,

Iowa, Kansas, Nebraska, North Dakota, and Wyoming. In some of these States, no satisfactory limestone deposits are available; in others, the market demands can be supplied more economically from sources outside the State than from development of local deposits. Limestones are widely distributed, and new plants could be estab-

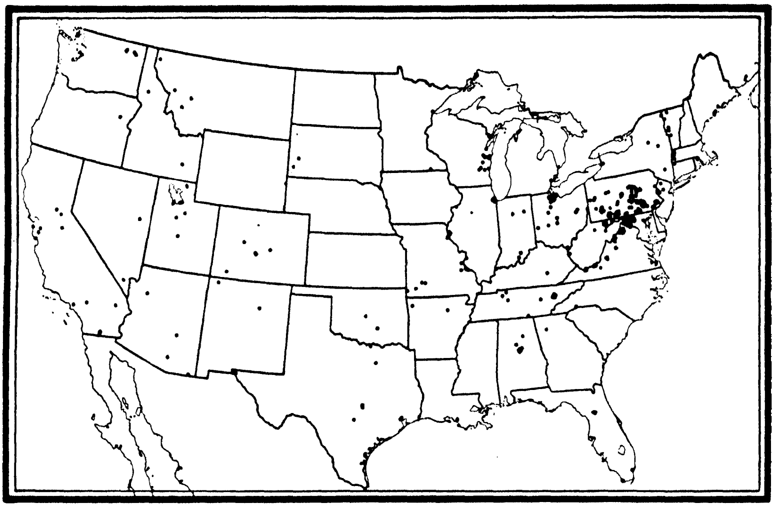

FIGURE 1.—Location of lime plants in the United States.

lished in many localities where they do not now exist, provided markets were large enough to justify operation.

PRODUCTION BY USES

Thirty years ago chemical and industrial plants consumed much less than half as much lime as the building trades. In 1941 the tonnage of lime applied to chemical and industrial uses was more than three times that used for building lime. On the other hand the quantity of lime used in agriculture has fluctuated only moderately, depending primarily on the buying power of the farmer. The most striking gain in any one use during 1941 was in metallurgical lime, which, under the stimulus of a steel industry operating at virtually 100 percent of capacity, increased 37 percent over 1940. The following table shows sales of lime, by principal uses.

Lime sold or used by producers in the United States, 1940–41, by uses

Use	1940				1941			
	Quantity		Value		Quantity		Value	
	Percent of total	Short tons	Total	Average	Percent of total	Short tons	Total	Average

Lime and other liming materials used in agriculture.—Because of its quick reaction and consequent speedy effect in promoting plant growth, lime is widely used as a soil conditioner and fertilizer. The same effect may be obtained by using finely divided uncalcined limestone or shells, but the action is slower. However, because of the low cost and ready availability of uncalcined limestone, it is used much more extensively than lime. The following table shows the quantities and values of various liming materials used in agriculture.

The effective lime content shown in this table has been calculated upon the basis of average percentages used by the National Lime Association, as follows: 85 percent of the quicklime (including lime from oystershells), 70 percent of the hydrated lime, 47 percent of the pulverized uncalcined limestone and oystershells, and 42 percent of the calcareous marl.

Agricultural lime and other liming materials sold or used by producers in the United States, 1940–41, by kinds

Kind	1940				1941			
	Short tons		Value		Short tons		Value

[3] Figures supplied by Fish and Wildlife Service.
[4] Preliminary figure.

Building lime.—Building-lime sales as a whole and by States are shown in preceding tables. Sales of building lime by kind or class and the value per ton in 1941 were as follows: Finishing lime, 452,522 short tons, $9.29; mason's lime, 464,564 tons, $8.20; for manufacture of prepared masonry mortars, 64,572 tons, $6.46; and for unspecified purposes, 83,941 tons, $9.87.

Chemical and industrial lime.—The use of lime in manufacturing and processing industries has attained great importance. Lime is regarded as an indispensable ingredient in hundreds of products and is deemed necessary as an active reagent in scores of important processes. These uses have been discussed largely from a statistical angle in a recent report [1] of the Bureau of Mines.

One of the important industrial uses is as a furnace flux and for other metallurgical applications. The quantities and average values per ton of lime applied to various metallurgical uses in 1941 were as follows: Flux for open-hearth steel manufacture, 998,968 short tons, $5.81; flux for electric steel furnaces, 52,883 tons, $7.05; flux for

[1] Bowles, Oliver, and Jensen, M. S., Limestone and Dolomite in the Chemical and Processing Industries: Bureau of Mines Inf. Circ. 7169, 1941, 15 pp.

smelting nonferrous metals, 76,112 tons, $5.86; ore concentration (including cyanidation), 159,634 tons, $5.81; wire drawing, 7,025 tons, $7.74; other uses (including unspecified), 72,277 tons, $6.40.

The quantity and value of chemical and industrial lime listed as "Other uses" in a previous table were reported for 1941 as follows:

Chemical and industrial lime sold or used by producers in the United States for "Other uses" in 1941

Use	Short tons	Value	Use	Short tons	Value
Acid neutralization	1,739	$14,222	Insecticides, fungicides, and disinfectants	81,955	$587,567

[1] Includes lime used in chocolate, cocoa, fruit juices, phosphate baking powders, and other food products not specified.

[2] Includes acids (unspecified), alcohol, alkalies (ammonium, potassium, and sodium compounds), amiesite road surfacing, bromine, calcium phosphate, cement manufacturing, explosives, fertilizer filler, heavy chemicals, magnesia from sea water, medicines and drugs, neutralization of phosphate, nicotine, poultry feed, precipitation of phosphate in vanadium manufacture, retarder, rock wool, soap and fat, Spanish whiting, starfish control, sulfur, tobacco, and wool pullers.

HYDRATED LIME

If quicklime (high-calcium) is exposed to water, it reacts readily to form hydrated lime according to the following equation $CaO+H_2O=Ca(OH)_2$. The reaction is accompanied by evolution of heat. The combination of lime and water upon a quantitative basis is as follows: 56 pounds of lime unites with 18 pounds of water to form 74 pounds of hydrated lime or "hydrate," as it is commonly termed. The user of hydrated lime may object to buying 18 pounds of water with every 56 pounds of quicklime and may on this account decide to buy quicklime and hydrate it himself. Some users do this, but in general the hydrating process is too precise an operation to be performed without adequate equipment or skill. For instance if too little water is added, part of the lime remains unslaked, which may cause trouble later. Unhydrated particles in a wall plaster, for example, will hydrate slowly, causing "popping" of the plaster. If, on the other hand, too much water is added, a damp, sticky, or muddy hydrate will be formed. Many lime companies are equipped with mechanical hydrators that automatically supply the exact quantity of water needed and agitate the product so thoroughly that virtually complete hydration of high-calcium lime is accomplished. Dolomitic (high-magnesium) lime hydrates less readily than high-calcium lime, therefore its preparation as a hydrate involves additional problems. Some lime producers have found it necessary to employ special equipment to attain adequate

hydration of dolomitic lime. Most users of hydrated lime prefer the product sold by lime producers.

Hydrated lime was reported by 166 plants for 1941 (161 reported for 1940). The increase from 1,385,825 short tons in 1940 to 1,590,159 in 1941 was accompanied by an increase of 18 cents a ton in average value. Three States—Ohio, Pennsylvania, and Missouri—produced 61 percent of the total. Production for a series of years and by States appears in the accompanying tables.

Hydrated lime sold or used by producers in the United States, 1937–41

Year	Plants in operation	Short tons	Value	
			Total	Average
1937	170	1,301,333	$10,344,470	$7.95
1938	165	1,169,804	9,111,575	7.79
1939	159	1,318,053	10,124,241	7.68

Uses.—Hydrated lime is utilized in many ways. Increased sales in all important categories were reported in 1941. The largest increases were for sugar refineries (52 percent) and tanneries (38 percent).

TRENDS IN PRINCIPAL USES

All major uses of lime increased during 1941, the greatest gain (35 percent) being for chemical and industrial purposes. Agricultural and building uses each gained 5 percent.

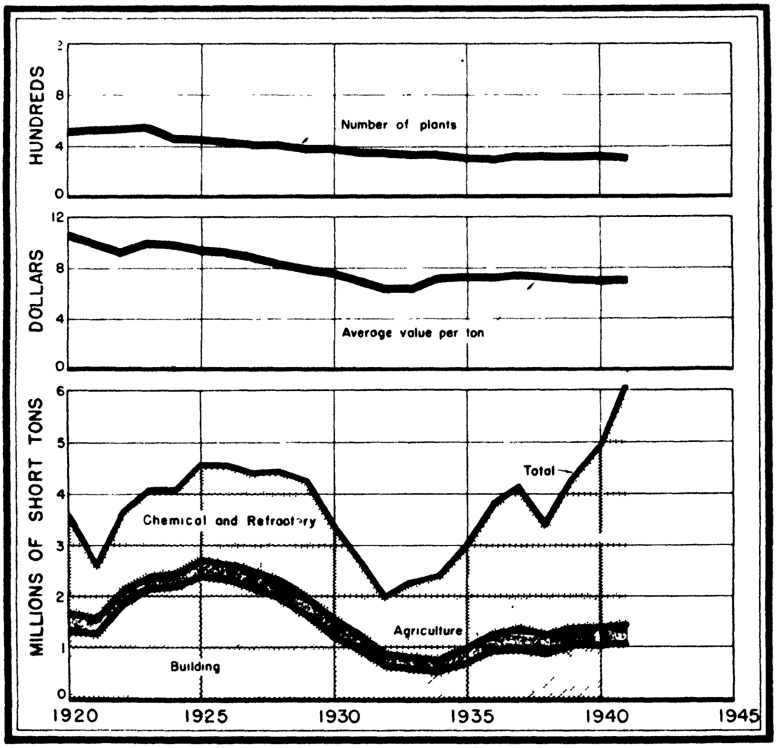

FIGURE 2.—Trends in number of active lime plants, average value per ton, and principal uses, 1920–41.

The gains in metallurgical and refractory lime were not consistent with each other—37 and 23 percent, respectively. The increase in chemical and industrial applications was accentuated further by large gains in the use of lime by manufacturers of calcium carbide and insecticides (50 percent over 1940). Trends in the principal uses over a 22-year period are indicated in figure 2.

A graphic comparison of the total quantity of lime consumed in building with new construction activity for the past 22 years is shown in figure 3.

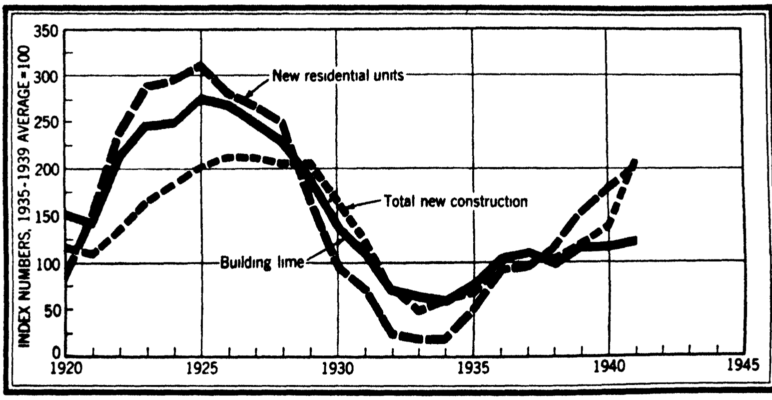

FIGURE 3.—Building-lime (quick and hydrated) value compared with total new construction and residential building, 1920–41. Data for new construction, 1920–41, from Department of Commerce. Data for new residential dwelling units (nonfarm) from Bureau of Labor Statistics.

Consumption of metallurgical lime has increased each year since 1932, except for the recession in 1938 (see fig. 4). The rate of increase has been greater in the past 3 years than the gain in steel-ingot output would indicate. This may be due in part to an increase in the use

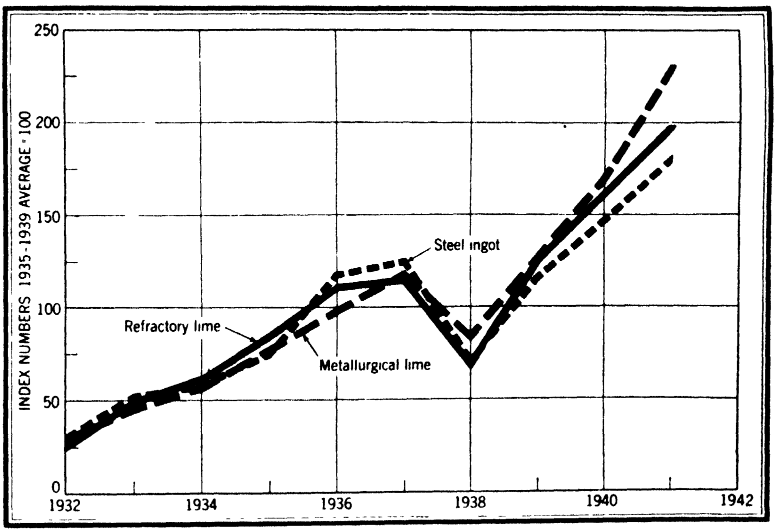

FIGURE 4.—Sales of metallurgical lime and refractory lime (dead-burned dolomite) compared with steel-ingot production, 1932–41. Index numbers for steel ingots computed by Federal Reserve Board from data of American Iron and Steel Institute.

of higher-phosphorus iron ores, as indicated earlier, and possibly to a decrease in the amount of scrap iron and steel used. The gain in production of metallurgical lime was accompanied by a less spectacular gain (20 percent from 1940 to 1941) in limestone for flux. Data on raw dolomite are given in the chapter on Stone.

SHIPMENTS

TOTAL SHIPMENTS

Sales, shipments, and supplies of lime available for consumption in continental United States, by States and groups of States that comprise approximate freight zones, are listed in the two tables that follow. Reshipments beyond original destinations are not indicated, and foreign shipments and tonnages for which distribution is not recorded are omitted.

Production of lime exceeds apparent consumption in 11 States, but only Ohio, Missouri, and Tennessee show large tonnages moving out of the State in excess of inward-moving shipments. Four leading States—Pennsylvania, New York, Illinois, and Michigan—consumed more than they produced.

Lime supplies available in continental United States in 1941, by States, in short tons

HYDRATED LIME

Apparent consumption of hydrated lime in the Middle Atlantic States has been high in recent years. During 1941 it rose in all regions, but the percentage of increase from 1940 to 1941 was greatest in the Upper Mississippi Valley States.

Shipments of hydrated lime from plants in continental United States and in Ohio in 1941, by destinations

Destination	From all plants		From Ohio plants		
	Short tons	Distribution (percent)	Short tons	Distribution (percent)	Percent of total shipments
Illinois, Indiana, Michigan, Ohio	339,021	21.5	231,979	43.0	68.4

PRICES

Reversing the downward trend of the preceding 3 years, 1941 prices increased in all major categories over 1940. The increase in value of agricultural lime was greatest—9 percent. This price is the highest since 1938. Building lime increased 3 percent and came within 1 cent of the highest price during the past decade (that in 1935). The price of refractory lime rose to a new high, with a 7-percent increase. Values for the past 10 years are compared in the following table.

Average values of lime according to uses, 1932–41 [1]

Use	1932	1933	1934	1935	1936	1937	1938	1939	1940	1941
Agricultural	\$5 59	\$5.36	\$6 66	\$6.73	\$6.26	\$6.74	\$6.52	\$6.11	\$5 71	\$6.24
Building	6 45	7 18	8 33	8.70	8.52	8.66	8.38	8.56	8 45	8.69
Chemical and industrial	6.13	5.73	6 52	6 50	6.42	6.47	6.53	6 23	6.20	6.23
Refractory	7 78	7.89	8.31	8.32	8 19	8.45	8.44	8.11	7.98	8.52
Total	6.28	6.28	7.16	7.28	7.18	7.30	7.21	7 06	6.95	7.06

FUEL RATIOS

A study of lime : fuel ratios of lime plants reporting for 1939 was made by Moyer [2] to show the comparative efficiency of various kinds of fuel used in the three general types of kilns. This study indicated that pot kilns were most efficient and rotary types least efficient.

[2] Moyer, Forrest T., Lime:Fuel Ratios of Commercial Lime Plants in 1939: Bureau of Mines Inf. Circ. 7174, 1941, 9 pp.

Shaft kilns using coke showed the highest lime : fuel ratio of any single type.

The accompanying table represents similar studies of reporting plants in 1940 and 1941. For each year, 60 percent of the active plants reported fuel ratios, representing over 75 percent of the total lime produced. A significant feature is the definite uptrend in efficiency of bituminous coal in shaft kilns and in rotary kilns producing dead-burned dolomite. Paradoxically, rotary kilns using bituminous coal, aside from those used to burn refractory dolomite, show a drop in lime : fuel ratio. In 1940 the greatest efficiency was attained by shaft kilns using coke, in 1941 by shaft kilns using anthracite. Kilns of all types using wood and oil decreased markedly in efficiency during 1941.

Lime: fuel ratios, by type of kiln and kind of fuel, for reporting plants, 1940–41

1940

Type of kiln	Kind of fuel	Reporting: Operators	Reporting: Plants	Number of kilns	Lime [1] produced (short tons)	Fuel used: Quantity [2]	Fuel used: Unit	Lime : fuel ratio [3]: Range reported	Lime : fuel ratio [3]: Calculated average

[1] Quantity of quicklime sold plus calculated equivalent quicklime contained in hydrated lime sold from reporting plants during year covered.
[2] Calculated from quicklime production and reported lime : fuel ratios.
[3] Reported and calculated as pounds of lime calcined by a unit quantity of fuel.

The quantity of lime burned by each of the several fuels increased in 1941 over 1940. The largest gain was in the use of natural gas, which more than doubled in importance. The tonnage of lime burned by bituminous coal decreased from 78 percent of the total in 1940 to 72 percent in 1941. Oil, wood, coke, and anthracite were used as fuels in burning 13 percent of the total lime in 1940 and 1941.

SIZE OF COMPANIES

A study of active commercial lime companies, comparing volumes of sales and numbers of companies in similar size groups, was made by Bowles and Coons in 1939.[3] This study indicated that companies producing less than 25,000 tons annually were decreasing in number and total output, whereas those producing more than 25,000 tons were increasing in number and output. The trend toward larger and fewer companies was interrupted during the early 1930's but was resumed a few years later. The accompanying table shows that the larger size groups gained greatly from 1936 to 1941. Companies producing over 50,000 tons showed the most spectacular increases in the last 5-year period, doubling in number and in production. In 1941 more than two-thirds of the total lime output of the country was reported by companies producing 50,000 or more tons.

Comparison of number of companies and sales of lime (including dead-burned dolomite) in the United States in 1926, 1931, 1936, and 1941, by size groups

Size group (short tons)	1926		1931		1936		1941	
	Companies	Short tons	Companies	Short tons	Companies	Short tons	Companies	Short tons
Less than 1,000	156	33, 385	134	35, 966	86	24, 414	77	24, 023

NEW DEVELOPMENTS

It is claimed that a new type of center burner now in use in shaft kilns gives increased output, better quality of lime, and higher fuel efficiency. Its greatest advantage, however, is its ability to utilize small stone, which is generally discarded as waste at plants where lime is burned in shaft kilns.

Unit coal pulverizers that discharge directly to rotary kilns—a type of equipment used at many cement plants—are now employed at lime plants.

Processes of pressure hydration have been perfected whereby 85 percent or more of the magnesia in dolomite is hydrated. The superhydrate, after supplementary treatment which varies in different plants, has unusual plasticity and sand-carrying capacity. Superhydration is especially advantageous in lime used for sand-lime brick manufacture and for wall plaster.

[3] Bowles, Oliver, and Coons, A. T., Graphic Survey of the Lime Industry, 1910–38: Bureau of Mines Inf. Circ. 7088, 1939, 8 pp.

Fundamental research is in progress at the University of Illinois in cooperation with the National Lime Association, involving X-ray work as well as studies by means of an electron microscope, on the properties of calcium and magnesium oxides and hydroxides.

Further progress has been made with the use of lime on stabilized roads. Hydrated lime mixed thoroughly with gumbo clay, wetted and compacted with a tamping roller, is said to provide a satisfactory base upon which an ordinary concrete or asphalt topping may be placed.

Bureau of Mines Information Circular 6884, Lime, published in 1936, describing the principal features of the lime industry, was revised and republished [4] in 1941.

FOREIGN TRADE [5]

Because of restrictions on publication of foreign trade data, figures for 1941 imports and exports are confined to the first 9 months of the year.

IMPORTS

The following tables show imports by kind for a series of years and by country of origin and customs district for 1940 and 1941.

Lime imported for consumption in the United States, 1937–41

Year	Hydrated lime		Other lime		Dead-burned dolomite [1]		Total	
	Short tons [2]	Value	Short tons [2]	Value	Short tons	Value	Short tons	Value
1937	1,174	$13,885	7,614	$76,720	9,083	$231,084	17,871	$321,689
1938	858	10,001	5,960	56,202	2,875	67,340	9,693	133,543
1939	1,148	11,242	6,546	60,660	186	4,260	7,880	76,162
1940	712	6,558	8,493	75,330			9,205	81,888
1941 (Jan.–Sept.)	555	6,364	8,610	72,496			9,165	78,860

[1] Classification reads "Dead-burned basic refractory material containing 6 percent or more of lime and consisting chiefly of magnesia and lime."
[2] Includes weight of immediate container.

Lime imported for consumption in the United States, 1940–41, by countries and customs districts [1]

Country	Customs district	1940		1941 (Jan.–Sept.)	
		Short tons [2]	Value	Short tons [2]	Value
Canada	Florida			15	$120

EXPORTS

Exports of lime in the past 5 years are indicated in the following table.

Lime exported from the United States, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	11,300	$122,895	1940	31,912	$311,619
1938	13,222	121,662	1941 (Jan.-Sept.)	32,444	318,541
1939	21,477	236,497			

CLAYS

By Paul M. Tyler and A. Linn [1]

SUMMARY OUTLINE

GENERAL SUMMARY

Shipments of almost every variety of clay from domestic mines again made new high records in 1941. Even before the World War of 1914–18, clay mining had become a substantial industry in the United States. In fact, during the 5 years immediately preceding the outbreak of hostilities in 1914, annual shipments of merchant clay averaged 2,381,965 short tons. This sizable tonnage, however, was worth only $3,736,487, and its low unit value testified that most of it was crude or ill prepared. Papermakers, pottery manufacturers, and other consumers of the better qualities of clay purchased their requirements abroad, and not until imports from overseas were endangered by submarines did American producers make serious efforts to improve their clays. Pioneered by the Bureau of Mines, beneficiation methods were worked out for refining Georgia clays so that they could be substituted successfully for imported clays.

During the interwar period, great progress was made in clay preparation, and the United States became potentially independent of foreign sources. The importation of high-grade clays continued but eventually was limited to certain localities where relative transportation costs made them cheaper or to certain branches of the ceramics industry (notably the manufacture of sanitary ware and semivitreous dinnerware) where changes in batch formulation are impeded by the excessive cost of possible spoilage compared with potential savings in cost of raw materials. Resumption of hostilities in Europe and the growing menace of submarines after September 1939 speeded the trend to displace imported with improved domestic clays. Meanwhile the rapidly expanding use of paper and the larger proportions of clay relative to other ingredients employed in the manufacture of paper, rubber, and other products increased the aggregate demand, so that the flow of kaolin and other high-grade clay from American mines has increased year after year. In 1941

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce. Domestic figures for fuller's earth compiled by R. W. Metcalf, of the Bureau of Mines.

the shipments of all kinds of domestic clay, excluding fuller's earth, totaled 7,018,056 tons valued at $25,193,893. Although this is only three times the 1909–13 annual average quantity it was worth almost seven times as much, the unit value being $3.59 a ton in 1941 compared with $1.57 before the first World War.

Bureau of Mines figures for clay shipments cover only a small fraction of the clay mined in the United States. No attempt is made to include the clay burned into common brick, build ng tile, sewer pipe, and other clay products at integrated plants situated at the mines or pits. On the assumption that it takes 3 tons of clay to make 1,000 brick, the production of common brick alone required over 22,000,000 tons of raw clay in the peak year 1925; notwithstanding diminished demand, structural clay products even now require from ten to fifteen million tons of raw clay a year. Only a little over half the total consumption of fire clay appears in the Bureau of Mines figures as shipments, because nearly half of the total (3,275,021 tons in 1941) is burned directly into refractories at pitside plants. About 4,000,000 tons of additional clay or shale are used in portland-cement manufacture, and most of this escapes inclusion in the annual clay statistics because it was neither sold nor shipped away from the mine. A rough calculation shows that shipments of what may be termed "merchant" clay comprised in 1941 only 20 percent and in some years not more than 10 percent of the total clay or shale mined in the United States.

Salient statistics of the clay industry in the United States, 1925–41

[1] Sales of bentonite included under "Miscellaneous clay" before 1930.
[2] Figures cover January to September, inclusive.

However, virtually all the kaolin, ball clay, and bentonite, plus a large and increasing percentage of the fire clay output, is marketed or used elsewhere by the producers. These clays are worth many times as much per ton as those used generally for heavy clay products; therefore, the total value of a merchant clay probably is higher than the book value of the clay used in integrated plants. Whereas the tonnage and value of china clay sold and used elsewhere for paper or pottery is reported by the Bureau of Mines as raw clay and credited as a product of the State in which it was mined, clay converted into common brick or sewer pipe is not reported as raw clay because doing so would result in duplication; it is included in the value of clay products as reported by the Bureau of the Census and included by

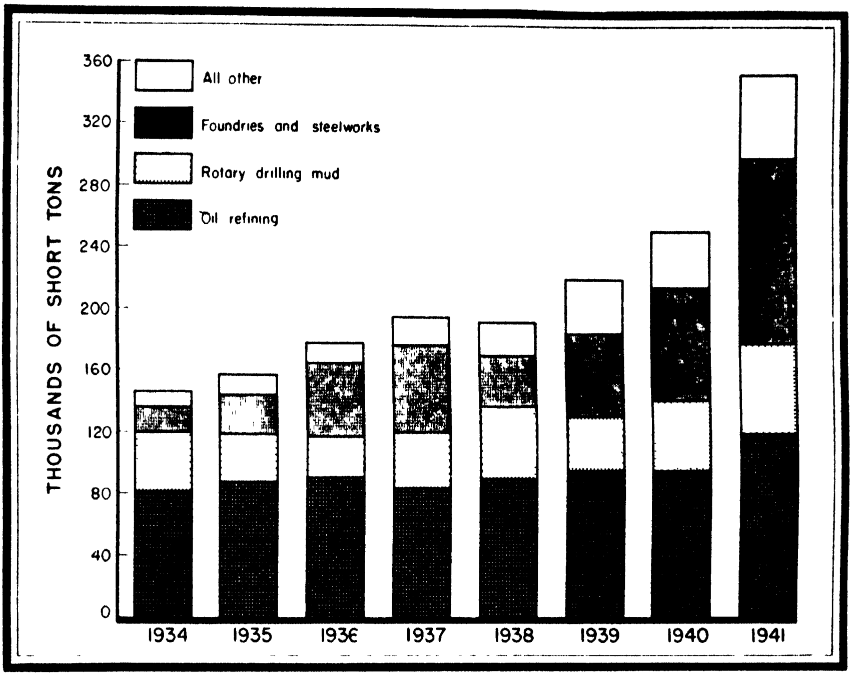

FIGURE 1.—Bentonite sold by domestic producers for specified uses, 1934-41.

the Bureau of Mines in its summarized mineral production statistics for the various States.

CONSUMPTION AND USES

The following table gives sales of specified domestic clays by kinds and uses in 1941, continuing the series begun in 1921. Data for total clay used in 1939 and earlier years by major uses (except refractories) were summarized in a bar chart in Minerals Yearbook, 1940 (p. 1268); and in the corresponding chapter of Minerals Yearbook, Review of 1940 (p. 1227), changes in distribution of sales of kaolin, by uses, were plotted. In the present chapter, figure 1 shows changes in distribution of sales of bentonite, by uses.

Clay (including fuller's earth) sold or used by producers in the United States in 1941, by kinds and uses, in short tons

Use	Kaolin	Ball clay	Fire clay and stoneware clay	Bentonite	Miscellaneous clay, including slip clay	Fuller's earth	Total
Pottery and stoneware:							
Whiteware, etc	102,346	148,600	15,886		509		267,341
Stoneware, including chemical stoneware		609	42,605				43,214
Art pottery, flowerpots, etc.	103	544	8,701		7,083		16,431

CHINA CLAY OR KAOLIN

Sales of domestic kaolin or china clay jumped to 1,087,848 short tons valued at $9,205,892 in 1941 from 833,450 tons valued at $6,994,106 in 1940. The tonnage topped that of the all-time record for the previous year by 31 percent and was more than double that of 1929. The paper industry alone required 110,000 tons more than in 1940 and consumed 56 percent of the total shipments. Percentage-wise, however, the consumption of clay for refractories, pottery, rubber, paint, and certain minor uses increased even more than shipments of paper clay.

Imports for the first 9 months of 1941—almost all English clay, which is used chiefly in paper, sanitary ware, and pottery and to a diminishing extent in porcelain and tile—amounted to only 66,945 short tons, with a foreign market value of $698,502. Import statistics for the last quarter cannot be published, but the 1941 total was undoubtedly less than the 105,567 tons imported in 1940. Average figures for 1925–29 show imports of 339,014 tons and domestic shipments of only 453,618 tons a year, and for 1909–13 the ratio of imports to domestic shipments was nearly 2 : 1 (261,266 and 132,114 tons a year, respectively).

Georgia was the leading kaolin-mining State in 1941, as usual, producing 787,013 tons or 72 percent of the national output; South Carolina (with 177,276 tons or 16 percent of the total) ranked second, and Pennsylvania (with 44,277 tons or 4 percent) third. In order of output, the other producing States were Florida, California, North Carolina, Virginia, Delaware, Illinois, Alabama, Maryland, Vermont, Utah, and Tennessee.

The location of kaolin mines in the United States is shown in figure 2.

Nine firms, operating 14 mines and each producing 30,000 tons or more, supplied 80 percent of the quantity and 84 percent of the value of the total sales in 1941; in 1940 approximately the same percentages of the quantity and value of the total shipments (which were smaller) came from 10 firms operating 15 mines. More than half of the firms reporting output in 1941 produced less than 4,000 tons each, and their aggregate contribution represented only 3 percent of the total tonnage shipped. The total output of the 42 smallest firms was less than that of any of the three largest firms in 1941.

Price quotations for domestic clays have remained virtually unchanged for several years, and readjustments of English clay prices have largely followed changes in ocean freight and insurance. Availability of bottoms was indicated by a reduction of $1 a long ton in the freight rate in the summer of 1941. The gradual increase in average value of domestic sales—from $7.94 in 1939 to $8.28 in 1940 and $8.46 in 1941—shows that the proportion of higher-grade clays is now greater rather than that prices have experienced a general rise.

More than 50 geographically separate kaolin deposits associated with the Spruce Pine alaskite have been found in Avery, Mitchell, and Yancey Counties, N. C., where total reserves of crude kaolin have been estimated at 51,000,000 tons, of which perhaps 10 percent is recoverable as refined china clay. The Tennessee Valley Authority and the Bureau of Mines, in collaboration with local producers, have

tested thoroughly the application of North Carolina kaolins, feldspar, and other materials in the manufacture of all-American dinner-ware and sanitary-ware bodies. The State geologist [2] published a brief report on the possibilities of producing high-grade ceramic products in western North Carolina.

For 1939 the Bureau of the Census reports (Preliminary Report, December 1941) the domestic production of kaolin as 751,000 short tons, or slightly less than the Bureau of Mines shipment figure of 780,000 tons which includes the output of operations too small for the Census to canvass as well as any quantities that were shipped from stock mined in earlier years. Including kaolin, ball clay, and certain miscellaneous clays (used principally for oil-well drilling muds), the Census reports a total production in 1939 of 1,050,000 tons of clay by the "Kaolin and ball-clay" industry, which comprised 95 pits or mines and 53 associated preparation plants in 19 States. Most of this was mined from open pits, although there were 5 small underground or combination underground and open-pit operations, 1 hydraulicking, and 1 dredge operation. The value of all products was $7,239,000.

[2] North Carolina Department of Conservation and Development, Division of Mineral Resources, Manufacturing China Clay Opportunities in North Carolina: Bull. 40, 1941, 24 pp

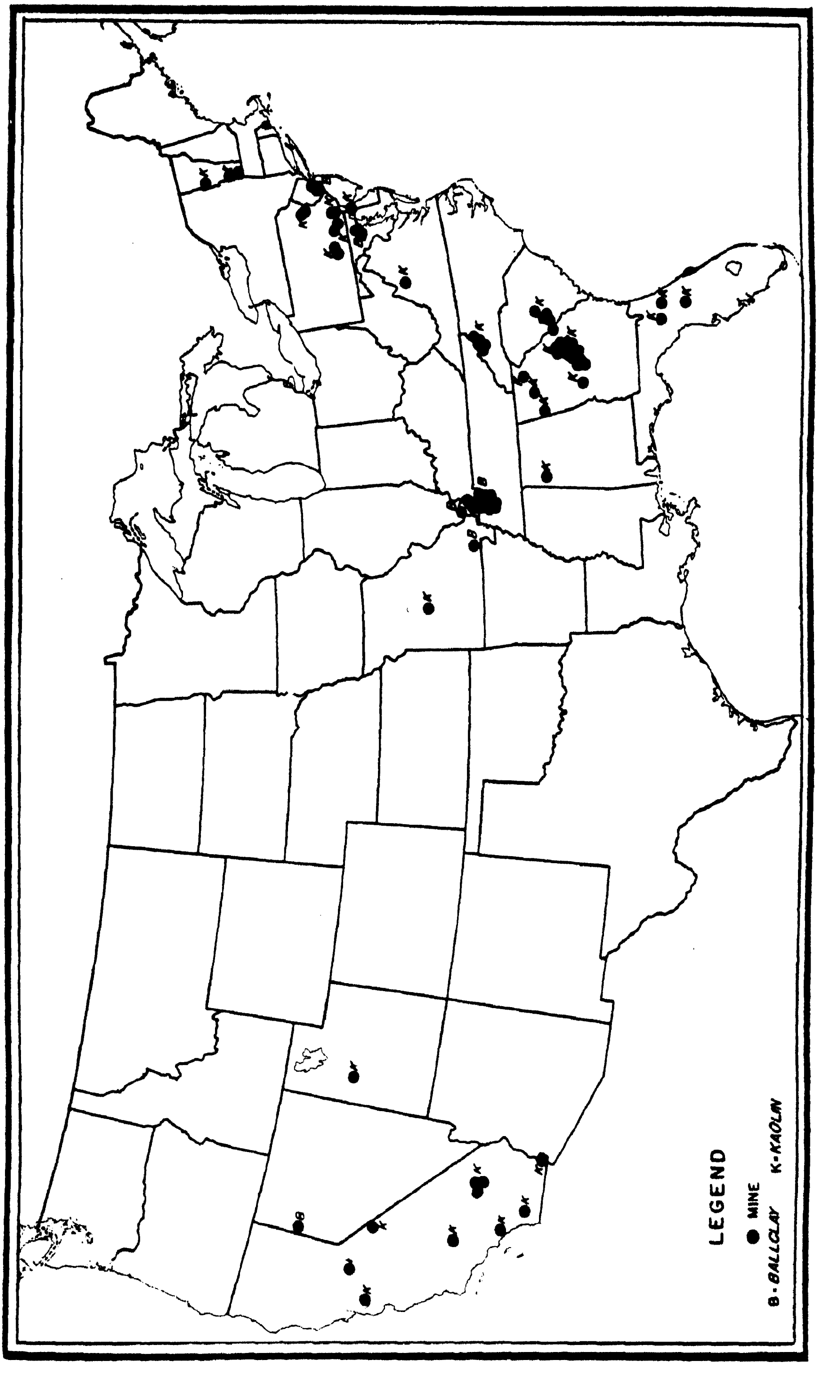

FIGURE 2.—Location of kaolin and ball-clay mines in the United States.

Wages were $1,830,000, and salaries (266 employees) were $637,000. Expenditures for supplies and materials ($896,000), fuel ($530,000), purchased electric energy (19,596 kw.-hr., $241,000), and contract work ($135,000) raised the reported expenses to an aggregate of $4,269,000. Buildings, machinery, and equipment erected or installed during 1939 cost $1,220,000. About 60 percent of the average of 3,168 wage earners were employed at operations in Georgia. Of the total number of man-hours worked by wage earners (5,987,000 or 7.3 hours per man per shift), about 40 percent was chargeable to mining and 60 percent to preparation. Average wage payments per hour ranged from 27 to 39 cents in Southeastern States and from 56 to 62 in Rocky Mountain and Pacific Coast States; the national average was 31 cents.

BALL CLAY

Reflecting increased activity by American potters and further displacement of imported clays, shipments of ball clay from domestic mines climbed to 198,445 short tons valued at $1,677,600 in 1941, or 41 percent in quantity and 57 percent in value over the former record of 140,077 tons and $1,065,432 in 1940, and continued a long ascent that has been interrupted seriously only once since 1932.

As in former years, most of the output in 1941 came from the Kentucky-Tennessee field. These two States furnished 94 percent of the total tonnage; the remainder was mined mostly in Maryland and New Jersey, although Mississippi, Missouri, and Nevada reported small shipments.

The location of ball-clay mines in the United States is shown in figure 2.

The sharp advance in unit values was notable; the national average sales realization rose to $8.45 a ton from $7.57 in 1940 and $7.28 in 1939. For Kentucky alone, the average sales price was $8.95, 13 percent higher than the 1940 average and the highest in any year since 1931. These increases, however, were not due entirely to a mark-up in quotations but also represent steady improvement in quality and the fact that much of the clay, instead of being shipped crude, is now being shredded or even pulverized by producers before shipment to consumers.

One company, with clay pits in both Kentucky and Tennessee, has long been the largest single producer; in 1941, although 17 companies reported shipments of ball clay, 86 percent of the total tonnage was furnished by 5 companies.

Imports of English ball clay in 1941, as indicated by statistics that cover only the first 9 months of the year, were substantially less than the 1940 imports which amounted in the full year to 32,141 short tons having a foreign market value of approximately $8 a ton, exclusive of freight, duty, and other charges. About half of the imported ball clay is used in sanitary ware. Formerly, it was demanded by virtually all manufacturers of electrical porcelain, vitrified china, and other high-grade products, but as domestic ball clays have been standardized and better-prepared they have been widely accepted by potters and ceramic engineers. Meanwhile, as noted in last year's chapter of this series, the ratio of ball clay to kaolin has tended to increase as a result of growing mechanization of the ceramic industry and new casting methods.

True ball clays are fine-grained, sedimentary clays that are characteristically plastic and develop high strength, usually accompanied by rather high shrinkage, in drying and firing. They vitrify at low temperatures, having a long firing range, and may range in P.C.E. values from cone 18 to cone 34. The borderline between ball clays and certain other clays, especially plastic fire clay, is not always sharply drawn, but all the better ball clays burn to a cream white or a sufficiently light buff so that they can be used in whiteware bodies.

FIRE CLAY

Jumping far ahead of the rising index of steel production and other barometers of consumption, shipments of fire clay (including a small quantity of so-called "stoneware" clay) rose 51 percent in 1941 to 4,167,567 short tons worth $10,455,909 from 2,765,247 tons and $7,046,746 in 1940 and the previous all-time record of 3,266,261 tons and $8,289,487 in 1929. These figures relate only to clay sold or shipped raw and do not include that burned into fire brick or clay products in integrated plants at the mine or pit, amounting to an additional 3,275,021 tons in 1941 and 2,039,377 tons in 1940.

Producers in 32 States shipped fire clay and stoneware clay in 1941, but as in former years more than one-fourth of the total was mined in Pennsylvania, and this State, together with Ohio and Missouri, furnished 63 percent of all the fire clay and stoneware clay sold or shipped raw and almost 70 percent of that made directly into fire brick or other products at the mines. Figure 3 shows the location of mines producing fire clay and stoneware clay in the United States.

As in other branches of the refractory industry, a few large companies are the principal miners of fire clay, each company owning and operating properties in various States and producing clay for use largely in its own plants. In addition, however, a score of other large or medium-size concerns are more or less completely self-contained and are important factors in their respective local markets. Of the total shipments in 1941, the 5 largest concerns furnished 36 percent; the next 5, 11 percent; and the next 15, 15 percent. Ranked in order of total clay, whether used at the pits or shipped, the 5 largest concerns represented 29 percent of the total tonnage; the next 5, 10 percent; and the next 15, 14 percent. Producers, including a great many small operators, totaled 499. Inspection of the returns indi-

cates a relatively large number of mining units producing 10,000 to 50,000 tons a year—implying that this may be an economical size of operation.

The main use of fire clay, of course, is in refractories. In 1941 demands were boosted not only by the record rate of operations at steel and nonferrous metal plants but also by the large amount of new construction. Great quantities of fire brick, for example, were needed for lining new blast furnaces and relining old ones and for all of their accessory equipment, including stoves for heating the blast, boiler plants, and coke ovens. The consumption of brick for rebuilding beehive coke ovens was exceptionally large. Under normal conditions byproduct ovens are more economical than beehive, but they take

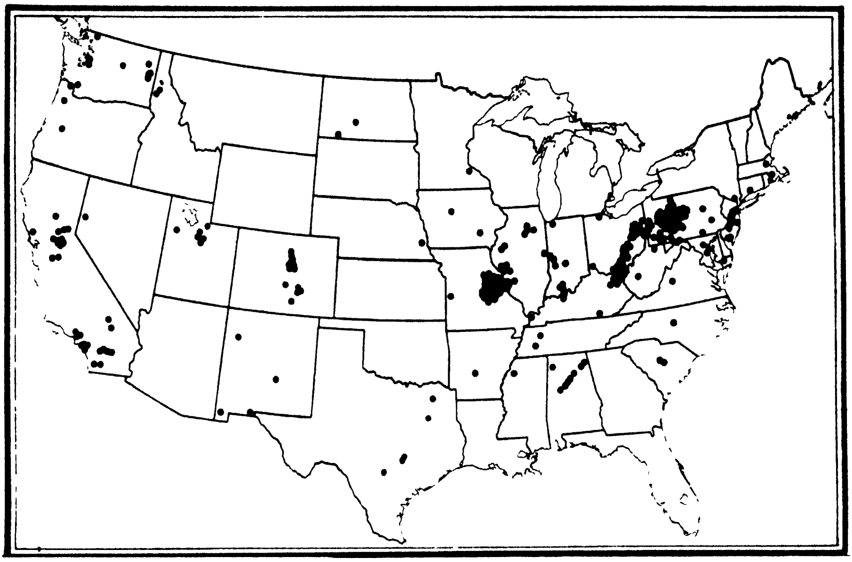

FIGURE 3.—Location of fire-clay mines in the United States.

longer to build. Many new furnaces had to be built for making shells, heat treating, annealing, or normalizing.

The Bureau of the Census reports (Preliminary Report, November 1941) a total of 4,074,000 tons of fire clay and 27,000 tons of stoneware clay produced in 1939 from 306 operations in 19 States. Pennsylvania was the largest producing State, contributing 25 percent of the total, Ohio was a close second with 23 percent, and Missouri ranked third with 17 percent. Underground mines supplied almost half of the total output, and operations combining open-pit and underground methods recovered about 10 percent; 42 percent was produced from open pits. In Pennsylvania 10 percent was produced from open pits. For the country as a whole, the output was 0.95 ton per man-hour for open pits and 0.63 for underground mines, but in Pennsylvania the ratio was 0.66 : 0.63. Wages ($3,365,838) of 3,655 wage earners and salaries ($498,506) of 255 other employees represented over 53 percent of the total value of products.

The Bureau of Mines figures for fire clay show a total of only 2,222,295 tons in 1939, but these data comprise only clay that was

sold or shipped away from pits. Including the 1,984,709 tons reported as burned into clay products at the mine, the Bureau of Mines canvass showed 4,207,004 tons or slightly more than the quantity reported by the Census which does not cover small operations whose sales or expenditures were less than $2,500 during the year.

Fire clay, including stoneware clay, sold or used by producers in the United States, 1939–41, by States

BENTONITE

Forty-one percent more bentonite was mined in the United States and sold during 1941 than during 1940, the former all-time record year for this remarkable clay, whose properties have only recently been put to extensive use. The output jumped to 354,028 short tons from 251,032 tons in 1940 and 219,720 tons in 1939; as recently as 1925, the total output was less than 5,000 tons. The value of the 1941 shipments increased to $2,451,900 from $1,919,461 and $1,702,393 in 1940 and 1939, respectively.

Owing to the speed-up in munitions plants, the main increase in consumption was in foundry and core sands; 121,283 tons (34 percent) of the total in 1941 were used for this purpose as against 74,135 tons (only 30 percent) of the total in 1940. Substantial increases were noted in virtually all uses, of which oil-refining (118,625 tons) and oil-well drilling muds (58,468 tons) ranked next to foundry work in quantities consumed.

Fully 60 percent of the 1941 tonnage was Type 1 swelling or Black Hills-type bentonite, which is mined principally in eastern Wyoming, western South Dakota, and California. Much of the remainder was of the nonswelling, nonsuspendible type (sub-bentonite), employed largely for oil refining after activation with acid and to a minor extent for foundry and other uses.

Figure 4 shows the location of bentonite mines in the United States. On the borderline between Type 2 bentonite and fuller's earth are various clays found in Texas and Utah, some of which are acid-sprayed or otherwise treated to enhance their natural bleaching or filtering properties when used in oil refining. Certain producers who formerly classified such clays as bentonite or miscellaneous clays now describe them as "fuller's earth."

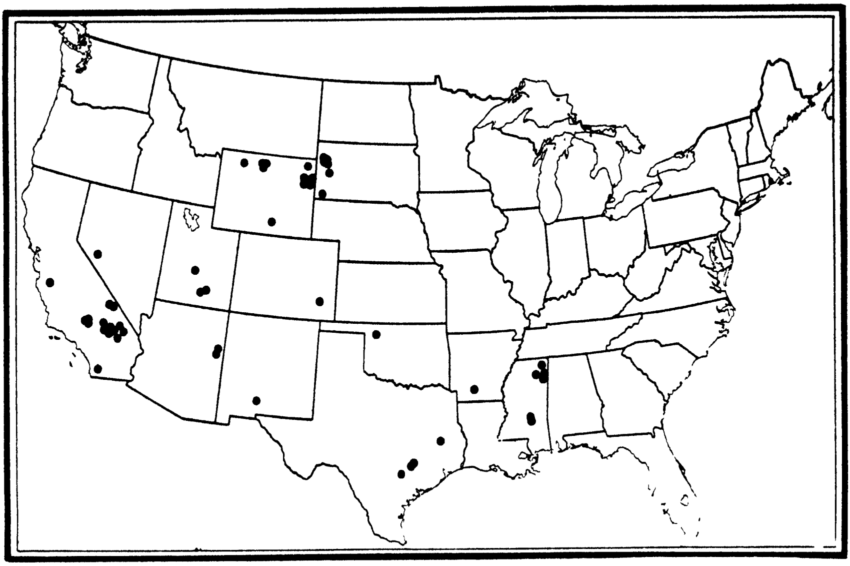

FIGURE 4.—Location of bentonite mines in the United States.

[2] Includes States indicated by "(1)."

The Nation-wide average price of $6.93 a ton f. o. b. mines in 1941 was much lower than the average of $7.65 in 1940; for Wyoming alone the average declined to $9.39 from $10.65 in 1940 and $10.22 in 1939. Trade-journal quotations, however, have remained for years at $8 a

ton for dried and crushed material in bulk and $10 in bags f. o. b. Wyoming mines, carlots. Actual prices likewise have continued unchanged at around $10.25 a ton for the widely used 200-mesh powder (f. o. b. Black Hills shipping point in 100-pound bags) and $7 a ton for 4- to 20-mesh material in bulk or $8.75 in bags. Bags are an important cost item but are not included in Bureau of Mines valuations. A steady decline in average unit values in recent years is due to larger quantities sold in carlots rather than less-than-carlots and possibly to a relative decline in the proportion of powdered clay. Sales of high-price, processed clay for specialized uses have increased but not enough to offset the effect of heavier sales of bulk products.

FULLER'S EARTH

Shipments of fuller's earth or natural bleaching clay increased in 1941 to 207,446 short tons valued at $2,111,674 from only 146,568 tons and $1,471,083 in 1940, or 42 percent in tonnage. Petroleum refining, which consumed 85 percent of the total in 1941 and 90 percent in 1940, increased only 9 percent. The quantity (21,840 tons) used for bleaching vegetable oils and animal fats nearly doubled, and the quantity (8,455 tons) used for other purposes more than doubled in 1941; but the apparent increase from 132,259 to 177,151 tons used in mineral-oil refining was due mainly to reclassification of their material by several producers.

The distinction between fuller's earth and other clays used in oil refining is largely a matter of opinion, as virtually all clays have some natural bleaching power and it is difficult to classify clays whose bleaching properties have been enhanced by acid-spraying or other treatment. Certain types of bentonite having little or no natural bleaching power are not fuller's earth, even though they are highly activated by acid treatment. In former years, 20,000 to 40,000 tons of borderline material produced principally in Texas has been classed as "miscellaneous clay" or "sub-bentonite", but in 1941 the trend was to emphasize its natural bleaching powers and so to call it "fuller's earth." For this reason, the 1941 statistics should not be interpreted as indicating a definite reversal of the downward trend owing to the substitution of other bleaching or clarifying agents and the adoption of oil-refining methods that reduce the requirements of natural bleaching clays. On the other hand, they may indicate that this trend is retarded or perhaps even has run its course.

The competition of acid-treated bentonite, activated bauxite, synthetic magnesium silicate, and other processed bleaching materials has intensified the importance of transportation cost, which often exceeds the total production cost of fuller's earth. Although clays having high bleaching power in their natural state are not widely distributed, location is a leading factor in successful operation of fuller's earth deposits. Florida and Georgia usually have furnished more than half of the total domestic output, although Texas, Illinois, or Nevada occasionally has outranked one or the other of these older sources as regards tonnage produced in a given year. In 1941, due in part to the inclusion of acid-sprayed earths and other borderline material, Texas was the leading producing State. The average value of the Texas clay, however, was only $9.26 a ton, f. o. b. mines, compared with $11.70 for the combined output of Florida and Georgia.

Notwithstanding definite improvement in quality and preparation of the fuller's earth marketed, the average value of the entire domestic output has ranged only slightly above $10 in recent years following an almost steady decline from $19.51 in 1920 to $13.64 in 1929 and a low point of $9.28 in 1933.

MISCELLANEOUS CLAY

As previously noted, Bureau of Mines data on shipments of "miscellaneous clay" do not include clay burned into clay products at the mines; in fact, the above classification is largely a "catch-all" designed to cover merchant clays not elsewhere listed in this chapter. The foregoing table of consumption by uses shows that most of the tonnage in this category is consumed in the manufacture of heavy clay products, followed by cement manufacture. The next largest item is rotary-drilling muds (in which it may be blended with bentonite), and substantial quantities are used in foundries and steel works. Very small quantities of slip clay are also included. The total shipments of miscellaneous clay in 1941 were 1,210,168 tons valued at $1,402,592, 70 percent more in quantity than in 1940. In addition, mine operators reported the consumption of 7,261,513 tons of clay burned into clay products at the mines. The summation of these figures (8,471,681 tons in 1941), however, does not cover the entire common-clay and shale industry of the United States, which, according to the Bureau of the Census (Preliminary Report, December 1941), produced 16,062,000 short tons of clay in 1939; the 1941 total output was doubtless larger than that in the census year 1939. The Census Bureau figures include 1,088,000 tons of clay used in the manufacture of cement but exclude 1,235,000 tons of clay and shale from pits worked in conjunction with limestone quarries and consequently considered by the Census as products of the limestone industry.

Additional information abstracted from the Census report follows:

The bulk of the tonnage was used in the manufacture of heavy clay products such as brick, hollow structural tile, architectural terra cotta, roofing tile, and sewer pipe. Open pits furnished 93 percent of the tonnage, underground mines 5 percent, and combination open-pit and underground operations, the remainder. Although common clay and shale are produced in 45 of the 48 States and in the District of Columbia about half the total quantity was mined in Ohio, New York, Pennsylvania, Illinois, Texas, North Carolina, and Georgia. Operations in Ohio employed 595 wage earners; those in Pennsylvania, 255; and those in Illinois, 172. Total monthly employment ranged from a low of 2,247 in February to a peak of 3,266 in June. The number of days operated ranged from only 74 in Oregon to

260 in South Carolina, and the tons of clay produced per man-hour averaged 2.93 to 3.36 for open pits and 1.04 for underground mines. In Ohio the output per wage-earner hour averaged 2.07; in New York, 5.92; in Pennsylvania, 2.66; and in Illinois, 3.35. The average hourly earnings of wage earners was 51 cents, ranging from 30 cents in the Southeastern States to about 65 cents in the Northeastern States.

The industry paid $2,793,000 in wages to an average of 2,906 wage earners during the year. Salaried employees, numbering 61 in October, were paid $94,000. Expenditures for supplies and materials amounted to $629,000; for fuel, $384,000; and for purchased electric energy, $214,000. In addition, $99,000 was paid for work done on contract. These reported expenses totaled $4,213,000. The cost of buildings erected and machinery and equipment installed in 1939 was $258,000.

CLAY PRODUCTS

The total output of the clay-products industries has varied greatly, but in recent years its value has averaged close to $250,000,000 annually, about half being structural products. Figure 5, furnished through courtesy of the National Clay Products Institute, Washington, D. C., shows the geographic distribution of clay-products plants in the United States.

A comprehensive report on the floor- and wall-tile industries was issued in 1941.[3]

The industries producing common brick and other heavy clay products were more active in 1941 than for many years previously, but their output still was not more than half that in the record year 1926. Further recovery is indicated. Masonry requires less metal than any other form of construction; and, particularly where permanence is desired, clay products are favorably considered. Adequate numbers of bricklayers and masons were available in 1941. Increased interest was shown in the larger building units, including tile up to

[3] U. S. Tariff Commission, Earthen Floor and Wall Tile: Rept 141, 2d Ser., 1941, 158 pp.

10 by 12 by 12 inches. In England, hollow tile filled with sand was an effective protection for store fronts and dwellings during aerial attack, and in the United States an air-raid shelter using steel-reinforced light tile has been designed. Loose piles of brick afforded excellent protection from bombs and have been recommended in some cases instead of sand bags owing to the shortage of burlap and the possible rotting of the fabric. Clay slabs laid over the attics or upper floors of residences are mentioned by the National Bureau of Standards as a protective measure against incendiary bombs.

The Wage and Hour Division of the United States Department of Labor issued a wage order effective September 1, 1941, establishing a minimum wage of 34 cents an hour for workers in brick factories, instead of the 30-cent hourly wage formerly in effect; approximately

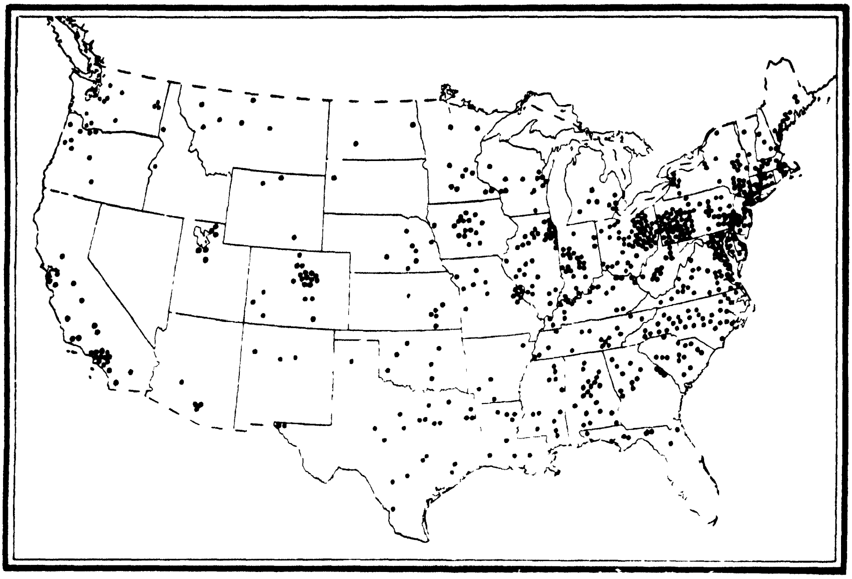

Figure 5.—Location of structural clay-products plants in the United States.

3,900 wage earners in 14 Southern States were benefited. Virtually all workers in the industry elsewhere in the Nation already received at least 40 cents an hour.

TECHNOLOGIC DEVELOPMENTS

Stepping up aluminum production to meet the ever-expanding needs of war-plant construction prompted reappraisal of clay as a possible source of the metal. Pure kaolin contains almost 40 percent alumina or roughly two-thirds as much as does bauxite, which hitherto has been considered the only economic ore of aluminum. Much of our bauxite comes from Surinam and after leaving the ship may be hauled hundreds of miles by rail to a chemical plant; the purified alumina then may go 2,000 miles farther to reach cheap electric power. Including mining, transportation, and treatment charges, purified alumina therefore costs $45 to $55 a short ton delivered at reduction plants in North America. As large clay deposits containing 30 per-

cent or more alumina occur within a radius of 100 miles of most of these reduction works or power sites, the incentive to use clay instead of bauxite is sufficient on financial grounds alone, wholly apart from the wartime problems of bringing sea-borne cargoes to American ports.

In 1940, the Tennessee Valley Authority announced that it had developed a process for making aluminum from clay, and it is said to have operated a pilot plant successfully for over a year, although no technical details have been released. Prof. Arthur Hixson, of Columbia University, recently described [4] a process for digesting selected high-silica clay with hydrochloric acid and decomposing the resultant product to get hydrochloric acid (which is returned to the process), and alumina (which can be reduced to metal in the conventional way).

ABRASIVE MATERIALS

By Robert W. Metcalf

SUMMARY OUTLINE

GENERAL CONDITIONS

The total value of products of the natural abrasives industries in 1941 was about 50 percent greater than in 1940. All types of abrasive materials except pulpstones and "oilstones and related products" made large gains over 1940 in value of sales. The value of pumice and pumicite sales established a new record, sales of ground sand and sandstone were the highest known except in 1917, and sales of emery were the highest since 1918. Garnet sales, except for 1937, had their greatest value since 1929.

Salient statistics of the abrasives industries in the United States, 1940–41

	1940	1941	Percent of increase, 1941 over 1940
Domestic production (sold or used by producers):			
Natural silica abrasives:			
Diatomite	(1)	(1)	
Tripoli	$366,569	$421,746	15
Quartz	176,390	228,587	30
Ground sand and sandstone	2,088,314	3,073,730	47
Special silica-stone products			
Grindstones and pulpstones	496,448	545,556	10
Oilstones and related products	(1)	(1)	
Millstones	6,558	15,579	138
Flint lining and grinding pebbles	(1)	276,042	
Natural silicate abrasives:			
Pumice and pumicite	449,914	669,514	49
Garnet	259,345	371,752	43
Natural alumina abrasives:			
Emery	9,349	42,484	354
Total natural abrasives [2]	[2] 3,852,887	[2] 5,644,990	
Total artificial abrasives [3]	10,142,691	16,444,319	62
Foreign trade:			
Imports	11,517,117	[4] 7,732,963	
Exports	1,605,961	[4] 1,884,938	

[1] Bureau of Mines not at liberty to publish figures. Average for diatomite for 1939–41 was $1,915,405.
[2] Excludes in 1940 value of diatomite, flint lining and grinding pebbles, and oilstones and related products and in 1941 value of diatomite and oilstones and related products, which the Bureau of Mines is not at liberty to publish.
[3] Includes some material produced in Canada; Bureau of Mines not at liberty to publish United States data separately.
[4] Figures cover January to September, inclusive.

Output of crude manufactured (artificial) abrasives broke all records for the second successive year, rising in 1941 to 279,030 short tons—54 percent above the former record year 1940; the total value also established an all-time high—$16,444,319, or 52 percent above the previous high value in 1929. All three types of manufactured abrasives for which figures are shown surpassed by large margins the former records achieved in 1940. The percentages of increase in 1941 compared with 1940 were: Silicon carbide, 36 percent; aluminum oxide, 50 percent; and metallic abrasives, 73 percent. In the period of 1941 (January–September), for which foreign trade data may be published, imports of diamond dust and smaller industrial diamonds continued unabated, receipts of corundum ore were larger than in any full year since 1936, emery ore receipts ceased entirely, and crude pumice receipts were virtually nonexistent. Total exports of natural abrasive materials in this period were greater than in the full year 1940, in spite of a large decrease in exports of grindstones and of emery and corundum abrasive wheels.

This chapter includes data for most of the materials used chiefly as abrasives, although certain clays, oxides, and substances mentioned later under "Miscellaneous mineral abrasive materials" are not included in the statistics presented herein. On the other hand, certain of the "abrasive materials" for which figures are included have important nonabrasive uses also.

On January 23, 1942, prices of both coated and bonded abrasive products virtually were fixed at the October 1941 level, at the request of the Office of Price Administration. Notification of any subsequent proposed increase in price and of the reasons for such action was required at least a month before the effective date of increase. Coated abrasives include sandpaper, garnet and emery cloth and paper, aluminous oxide cloth, and similar items, whereas bonded abrasives include manufactured grinding wheels, honing sticks, sharpening stones, and similar products.

The effect of grinding, lapping, superfinishing, and similar polishing operations upon metal surface finishes was studied by means of electron diffraction, microscopic experimentation, and corrosion tests.[1] The use of pumice and diatomaceous earth and other natural products, as well as byproduct and processed or expanded aggregates, in lightweight concrete was discussed by Moyer.[2] The occurrences and uses of silica in its many forms, including vein quartz, quartz crystals, tripoli, diatomaceous earth, and gem and ornamental varieties, were described.[3]

NATURAL SILICA ABRASIVES

Diatomite.—The Bureau of Mines has not been at liberty to publish annual production figures for diatomite since 1926. Total output (sales) for 3-year periods, however, may be shown. Total sales for the three most recent of such periods were as follows—1939–41: 360,502 short tons valued at $5,746,216; 1936–38: 279,645 tons valued

[1] Wulff, J., Metallurgy of Surface Finish: Proc. Conf. Friction and Surface Finish, June 1940, pp. 13–21; abs. Bull. British Nonferrous Metals Research Assc., No. 138, December 1940, p. 332; Ceram. Abs. (Am. Ceram. Soc.), vol. 20, No. 9, September 1941, p. 211.

at $4,377,353; and 1933–35: 244,342 tons valued at $3,618,428. Sales during 1941 were at a considerably higher level than in prior years.

California and Oregon remained the principal producing States; other States in which diatomaceous earth was produced in 1941 were Florida, Idaho, Nevada, New Mexico, New York, and Washington (see fig. 1).

Although new uses constantly are being developed, the chief marketing outlets for diatomite are as filter aids; as polish ingredient, especially silver polish; as an insulating material, either in board or as block; and as fillers or admixtures in a variety of products. The diatomaceous earth operations of the Dicalite Co. in Oregon were reported by Manning, [4] who outlined the equipment and processes employed in treatment as well as the uses for which the finished product is adapted. The winning of commercial diatomite from fresh-water bog deposits in Florida, the various grades marketed, and the uses of each type were described.[5]

Quotations on diatomite, as reported in Engineering and Mining Journal Metal and Mineral Markets, remained unchanged throughout 1941, as follows: Crude dried diatomite f. o. b. mines (Nevada), in bulk $7 per ton, in bags $12; low-temperature insulation, $19 per ton; high-temperature insulation $40.

The properties of diatomaceous earth and its uses as a filtering medium, a carrier for catalysts, and a filler, and in the plastics and papermaking industries were discussed by Hall.[6] The effect of chlorine on diatomaceous earth was studied in Great Britain.[7] Using a process developed by the Bureau of Mines,[8] a pilot-plant run on a Maryland diatomite was made to ascertain operating costs and to determine the feasibility of producing this material on a commercial scale.[9]

Use of diatomaceous earth instead of flint in five different types of ceramic glazes resulted in improved gloss and an off-white color, according to Keith.[10] Diatomite as a base for chemical pigments[11] and its use in the match industry[12] were described.

Diatomaceous silica, also known as kieselguhr, was first used in the sugar industry in the United States about 25 years ago. Gradually increased numbers of units of modern filtration equipment were installed, especially after the introduction of faster-flowing filter aids in 1923. By 1930 filter aids of diatomaceous earth were being used by nearly all sugar refineries in the United States and Canada

and by many refineries and other types of sugar factories in different countries,[13] particularly beet-sugar factories. Methods and equipment have frequently been developed and improved. Use, equipment, modern procedures, and the results obtained in sugar refineries by diatomaceous earth filter technique were discussed in a series of articles in the technical press.[14]

Tripoli.—The total quantity of tripoli (including Pennsylvania rottenstone) sold was slightly less in 1941 than in 1940—29,301 short tons compared with 30,212 tons; the value of sales, however, rose 15 percent to $421,746 from $366,569 in 1940. Tripoli or amorphous silica was produced in the same States as in 1940, the output coming largely from Illinois, Missouri, and Oklahoma; other States reporting production were Arkansas, California, Pennsylvania (rottenstone), and Texas.

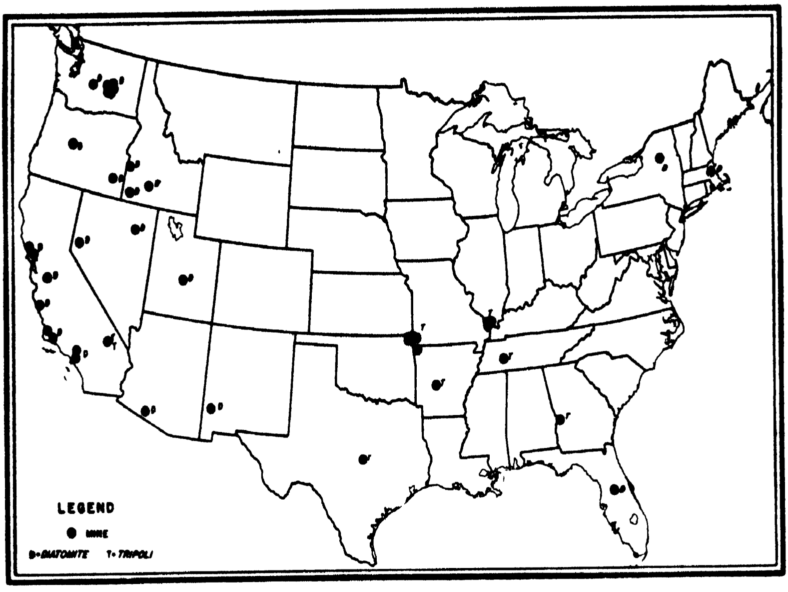

FIGURE 1.—Geographical distribution of diatomite and tripoli mines in the United States.

According to Engineering and Mining Journal Metal and Mineral Markets, prices of tripoli remained constant during 1941, as follows [15]: Once-ground through 40-mesh, rose- and cream-colored, $14.50; double-ground through 110-mesh, rose and cream, $16; air-floated through 200-mesh, $26.

[2] 1939: Foundry facing, oil-well drilling mud, and unspecified; 1940: Filter block, foundry facing, and unspecified; 1941: Foundry facing and unspecified.

Abrasives and fillers remained the largest outlets for tripoli in 1941, each showing a substantial gain over 1940, and combined they represented 80 percent of the total sales compared with 62 percent in 1940. Oil-well drilling made a small gain over 1940, whereas concrete admixture decreased as did "other uses," which in 1941 comprised foundry and unspecified uses.

Quartz.—The output of crude, crushed, and ground quartz from pegmatite veins or dikes and from quartzite in 1941 increased to 41,685 short tons, valued at $228,587, or 31 percent in tonnage and 30 percent in value over 1940. Production was much higher than in any year since 1920. The gain in 1941 in total sales of quartz was due to the greatly increased sales of crude and crushed material, as 19 percent less ground quartz was sold than in 1940; however, except for 1940, the quantity was larger in 1941 than in any year since 1935.

Quartz (crude, crushed, and ground) [1] *sold or used by producers in the United States, 1937–41*

Year	Crude		Crushed		Ground		Total

[1] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.

An output of quartz in 1941 was reported from 15 States compared with 13 in 1940. (See fig. 2). No sales in 1941 were reported from Virginia; and States producing in 1941 but not in 1940 were New Hampshire, Ohio, and Texas. Otherwise the same States furnished quartz in both years.

Ground sand and sandstone.—Sales of ground sand and sandstone in 1941 (487,665 short tons) were the largest ever recorded except in the war peak year 1917; the value of sales ($3,073,730), however, was over two and a half times that in 1917 and 43 percent greater than the previous high value of $2,146,464 in 1936. States producing substantial tonnages in 1941 were Illinois, New Jersey, Ohio, and Pennsylvania (see fig. 2).

[2] 1940: Missouri, North Carolina, and Wisconsin; 1941: California, Missouri, and Wisconsin.

As in 1940, the three principal uses for ground sand and sandstone in 1941 were pottery, porcelain, and tile (38 percent of the total), abrasives (21 percent), and foundries (16 percent), or 75 percent of the total quantity marketed for these uses compared with 83 percent in 1940. Consumption for all the uses indicated in the accompanying table showed considerable increases over 1940; for example, the amount used in glass manufacture, fourth-largest use in 1941, was over three and a half times that consumed for this purpose in 1940.

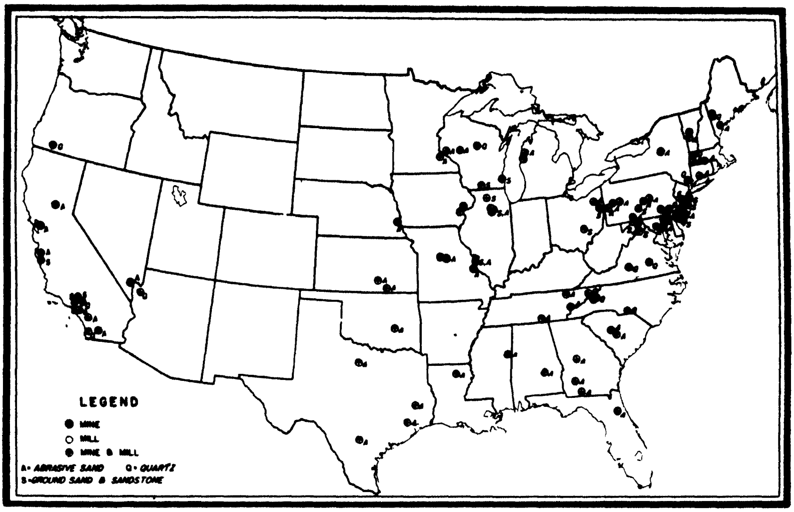

FIGURE 2.—Geographical distribution of plants producing quartz, abrasive sand, and ground sand and sandstone in the United States.

Ground sand and sandstone sold or used by producers in the United States in 1941, by uses

Use	Short tons	Value: Total	Value: Average per ton
Abrasive:

	487, 665	3, 073, 730	6. 30

Abrasive sands.—Production of natural sands with a high silica content, employed for sand blasting, scouring stone, grinding glass, sandpaper, and other abrasive uses, rose in 1941 to 1,001,814 short tons valued at $1,388,966 from 856,309 tons valued at $915,925 in 1940, or 17 percent in tonnage and 52 percent in value. It was only slightly less than that in 1937—1,067,178 tons valued at $1,440,736. The 1941 total includes 371,049 tons of blast sand valued at $912,626—45 percent more in quantity and 53 percent in value than the 256,104 tons valued at $597,198 reported for 1940.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and pulpstones.—Total sales of grindstones and pulpstones in 1941 rose to 15,536 short tons valued at $545,556, or 17 percent in tonnage and 10 percent in value over 1940, although the output of pulpstones fell sharply. Both the tonnage and value of grindstones sold in 1941 were over 50 percent greater than in 1940 and higher than in any recent year. Approximately equal to the 1930 output, the total for 1941 remained considerably under the annual production for the decade ended with 1929. Owing chiefly to the severe competition of manufactured pulpstones made from aluminum oxide, production of natural pulpstones decreased 57 percent in tonnage and 47 percent in value from 1940. As in other recent years, grindstones were quarried in Ohio and West Virginia and pulpstones in Washington and West Virginia.

Grindstones and pulpstones sold by producers in the United States, 1937–41

Year	Grindstones		Pulpstones		
			Quantity		Value
	Short tons	Value	Pieces	Equivalent short tons	
1937	11,617	$352,377	761	2,924	$220,331
1938	4,653	149,019	417	1,553	90,987
1939	7,917	257,350	672	2,517	169,025
1940	8,790	284,809	901	4,533	211,639
1941	13,573	434,208	685	1,963	111,348

Oilstones and related products.—Sales of natural sharpening stones—including oilstones, whetstones, scythestones, and rubbing stones—decreased somewhat in 1941 compared with 1940. As in 1940, however, the Bureau of Mines is not at liberty to publish the figures. States that contributed to the total in 1941 and the type of stone reported from each were as follows: Arkansas, oilstones and whetstones; Indiana, scythestones and rubbing stones; New Hampshire, scythestones, whetstones, and lathestones; and West Virginia, rubbing stones.

Oilstones and other whetstones, hones, scythestones, and rubbing stones sold by producers in the United States, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	810	$112,841	1940	(1)	(1)
1938	511	130,277	1941	(1)	(1)
1939	620	115,805			

1 Bureau of Mines not at liberty to publish figures

Millstones.—The value of millstones sold in 1941 rose to $15,579, or 138 percent above 1940 and 41 percent above 1939—the highest recent year. However, it was much less than the annual values recorded before 1930. In 1941 millstones were produced in Ulster County, N. Y.; Rowan County, N. C.; Montgomery County, Va.; and near Morgantown, W. Va. (see fig. 3). Output of chasers also was reported by two producers in New York.

Value of millstones, chasers, and dragstones sold by producers in the United States, 1937–41

Year	New York		Other States [1]		Total	
	Producers	Value	Producers	Value	Producers	Value

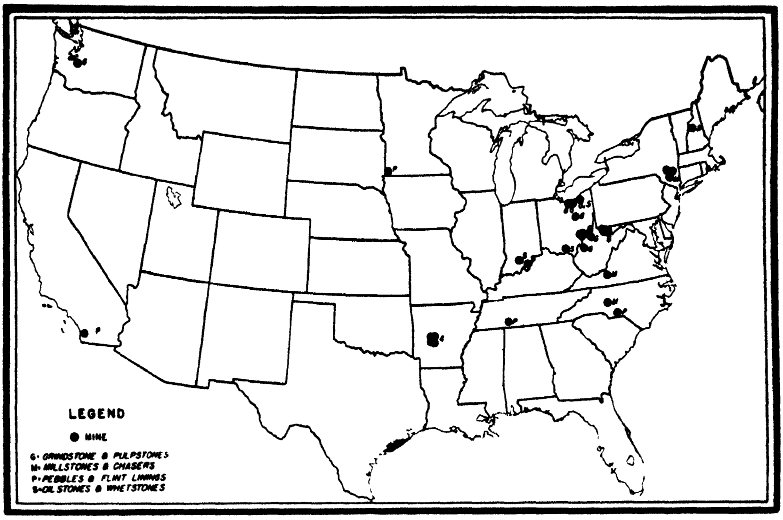

FIGURE 3.—Geographical distribution of sources of grindstones and pulpstones, millstones and chasers, pebbles (grinding), and tube-mill linings (flint linings), and oilstones and whetstones in the United States.

Grinding pebbles and tube-mill liners.—Because of the curtailment of receipts of foreign pebbles and liners—chiefly Danish and French pebbles and Belgian silex liners—strenuous efforts have been made to locate and market domestic materials. For many years, the principal domestic supply has come from quartzite deposits in Minnesota or from southern California beaches. Materials tested include shaped liners and tumbled cubes of granite, quartzite other than the Minnesota material, and quartz pebbles and other rounded or shaped rocks from Canada, Newfoundland, and the United States. Some of these have given, under difficult conditions, service as good as or better than the imported products.

In response to this increased interest in domestic sources, a number of new producers entered the field, and the sales of grinding pebbles and tube-mill liners in 1941 rose to 16,972 short tons valued at $276,042—somewhat higher than the tonnage and more than twice the value in 1917, the previous high year. Of the total for 1941, grinding pebbles represented 13,561 tons valued at $221,826 and tube-mill liners 3,411 tons valued at $54,216.

In 1941 the principal commercial producer of grinding pebbles and tube-mill liners was the Jasper Stone Co., Sioux City, Iowa, which marketed liners and artificially rounded quartzite pebbles from near Jasper, Minn. In California, John C. Momand, Carlsbad, again produced beach pebbles (mostly of granite, with no flint pebbles); the Crystal Silica Co., Los Angeles, and the Ocean Rock & Sand Co., Oceanside, also sold some grinding pebbles. Charlotte Chemical Laboratories, Inc., Charlotte, N. C., which in 1940 operated as the Southern Products & Silica Co., produced granite liners, rounded granite cubes, and milled-silica (quartz) pebbles; the Harris Granite Quarries Co., Salisbury, N. C., marketed both liners and rounded granite cubes; and Peeler & McCombs, Faith, N. C., sold granite pebbles and liners. Quartzite liners were produced by J. Howard Swaim, 918 Cotton States Bldg., Nashville, Tenn., from deposits near Iron City, Tenn.

Texas flint pebbles were marketed in 1941 by Philip S. Hoyt, Columbus, Tex., and the Dezendorf Marble Co., Austin, Tex.; these pebbles are said to be nearly as tough as the Danish pebbles formerly imported. Philip S. Hoyt produced some liners also. Another new source was the Baraboo Quartzite Co., Baraboo, Wis., which produced quartzite pebbles in Sauk County, Wis.

In 1942 Texas pebbles are being marketed also by The Richard L. Cawood Co., 1250 St. George St., East Liverpool, Ohio. Grinding pebbles produced near Elmore, Ala., are sold through the Great Lakes Foundry Sand Co., United Artists Bldg., Detroit, Mich.

NATURAL SILICA ABRASIVES

Pumice and pumicite.—Sales of pumice and pumicite in 1941 rose to 117,310 short tons valued at $669,514—an all-time high in both quantity and value; they were 42 percent greater in tonnage than in 1940 and 32 percent above 1939, the previous record year. The total value in 1941 surpassed by 49 percent the 1940 high of $449,914. This large increase reflects both the greater use of pumice as a concrete aggregate in building and the more careful preparation of domestic pumice and its acceptance by consumers in place of the high-quality abrasive grades formerly imported.

Pumice and pumicite sold or used by producers in the United States, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	71,007	$301,936	1940	82,407	$449,914
1938	65,742	312,886	1941	117,310	669,514
1939	89,159	424,780			

Production of pumice and pumicite in 1941 was reported from California, Kansas, Nebraska, New Mexico, Oklahoma, Oregon, and Texas (see fig. 4).

Pumice and pumicite used for concrete aggregate and admixture increased in 1941 to 56,159 short tons, or 155 percent above the 1940 figure. Use in acoustic plaster was 32 percent greater than in 1940. Consumption in abrasives, however, was slightly less than in 1940, although the value increased 62 percent—49,031 tons valued at $392,364 in 1941 compared with 50,195 tons valued at $242,331 in 1940 (see fig. 5).

Pumice and pumicite sold or used by producers in the United States, 1939–41, by uses

Use	1939		1940		1941	
	Short tons	Value	Short tons	Value	Short tons	Value
Abrasive:

	89,159	424,780	82,407	449,914	117,310	669,514

[1] Included under "Other uses."
[2] 1939: Asphalt, heat or cold insulation, or other abrasive use, insecticide, building tile and blocks, roofing, stucco, and unspecified uses; 1940. Asphalt, heat or cold insulation, insecticide, stucco, lime mortar, and unspecified uses; 1941: Asphalt, insulating mediums, insecticide, paint products, and unspecified.

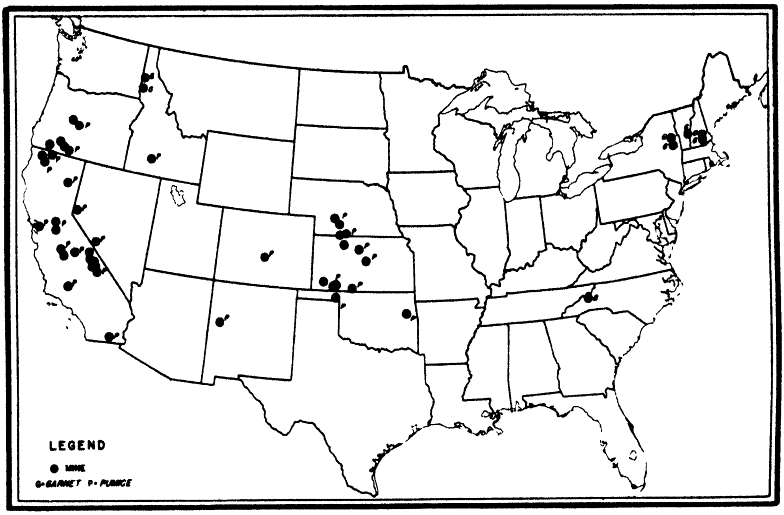

FIGURE 4.—Geographical distribution of garnet mines and pumice and pumicite mines in the United States.

The European War cut off supplies of Italian pumice, which usually has made up the bulk of the high-quality abrasive pumice sold in the eastern United States. Suitable domestic pumice was located in California. Increasingly difficult transportation conditions, however, led to the purchase by eastern importers of the pumice mill at Grants, N. Mex., heretofore operated by the Barnsdall Tripoli Co., Seneca, Mo. Under the name of the Pumice Corporation of America, this plant is now shipping high-grade pumice for abrasive use to eastern markets at an all-rail rate said to be comparable with rates by rail-water routes formerly utilized[16] from California.

A brief paper by Adams [17] described the chemical and physical properties, uses, and economics of pumice and volcanic ash. The

[16] Bureau of Mines, Mineral Trade Notes: Vol. 13, No. 1, July 19, 1941, pp. 22–23; Rock Products, vol. 42, No. 8, August 1941, p. 120.
[17] Adams, James A., Pumice and Pumicite: Oregon State Dept. Geol. and Min. Ind., G. M. I. Short Paper 6, Portland, Oreg., 1941, 7 pp.

pumice deposit of the West Coast Pumice Co. near Chemult, Oreg., and its commercial utilization were described.[18] Pence [19] discussed the advantages of volcanic ash as a ceramic body constituent. After electromagnetic treatment, pumicite may be used in place of feldspar in ceramic bodies whose color has secondary importance. The mechanical strength of pumicite bodies is higher than that of feldspar bodies. Shrinkage is also somewhat higher. Other properties of ceramic mixes containing pumicite are similar to those using feldspar.

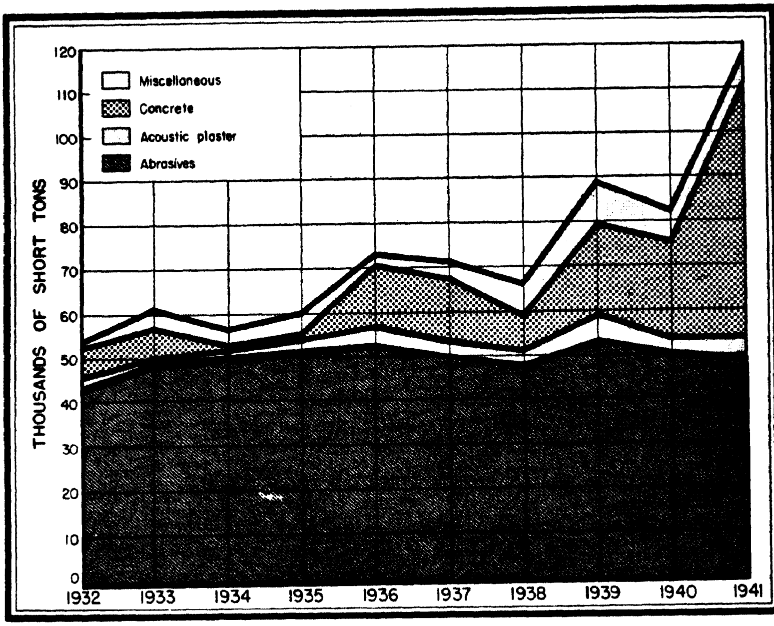

FIGURE 5.—Trends, by uses, of pumice and pumicite sold or used by producers in the United States, 1932–41.

Garnet.—Abrasive garnet sold or used by producers in the United States in 1941 totaled 5,501 short tons valued at $371,752—a gain of 17 percent in tonnage and 43 percent in value over 1940 and higher than in any year since 1929 (fig. 6). Increased industrial activity on account of the munitions program contributed to the increased demand. The outlook for further expansion during 1942 seems favorable. In 1941, as in 1940, output of garnet produced for sale came from New York, North Carolina, Vermont, and Idaho (see fig. 4). After reorganization, Mas-Celo Mines, Inc., Burnsville, N. C., producers of byproduct garnet, took over and continued operation of the properties of Celo Mines, Inc.

Market quotations for garnet at the beginning of 1941, as reported by Engineering and Mining Journal Metal and Mineral Markets, were as follows: New Hampshire, f. o. b. mines, per ton, concentrate, $30; grain, $80 to $140; New York, Adirondack garnet concentrates, grain, $85 per ton; Spanish grades, c. i. f. port of entry, $60 (nominal). These prices held firm throughout the year except for New Hampshire

[18] Mining World, Oregon Pumice Deposit Put to Commercial Utilization: Vol. 3, No. 1, January 1941, p. 30.

[19] Pence, Forrest K., White-Firing Texas Volcanic Ash as a Body Ingredient: Bull. Am. Ceram. Soc., vol. 20, No. 10, October 1941, pp. 327–329.

concentrate, which after August 14 was quoted at $35 per ton, and Spanish garnet which after June 5 rose to $70 per ton, c. i. f. port of entry.

Abrasive garnet sold or used by producers in the United States, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	4,863	$382,535	1940	4,716	$259,345
1938	2,669	191,658	1941	5,501	371,752
1939	4,056	278,534			

A popular account of the garnet, its forms, varieties, and mineral associations, was published.[20] Operations of the Barton Mines Corporation on Gore Mountain near North Creek, N. Y. were described.[21] The garnet-bearing rock is broken by blasting and hauled to a ramp which leads into the mill. After it passes through a roll crusher, the dirt and rock are removed by washing, and the clean garnets are graded for size, dried, and packed in bags for shipment. Some of the product is crushed further, according to customers' orders, but the greater part is sold in sizes as produced. Production averages 12 to 15 tons daily from rock containing 5 to 12 percent garnet.

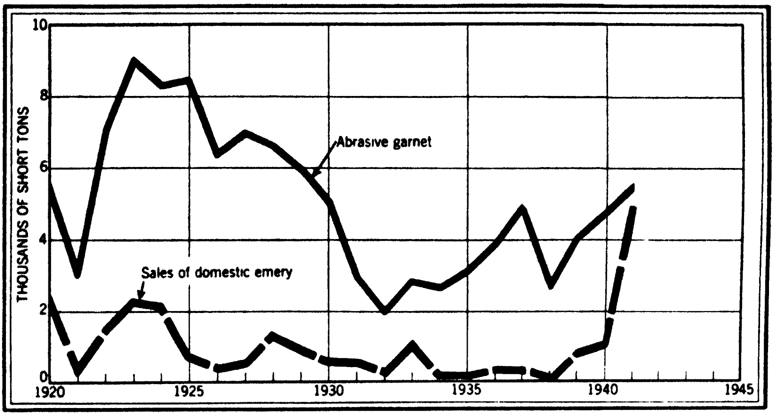

FIGURE 6.—Marketed production of abrasive garnet and domestic emery in the United States, 1920–41.

NATURAL ALUMINA ABRASIVES

Corundum.—Corundum exports from South Africa, chief source of world supply, were consigned chiefly to the United States in 1941. A large plant for the treatment of boulder corundum, to cost about £20,000, was being built in 1941 at Pietersburg, in Northern Transvaal. It is proposed to distribute corundum from Pietersburg direct to Australia, India, and other countries that hitherto have been supplied by way of the United States.[22]

[21] Diesel Power and Diesel Transportation, Mining Garnet with Diesel Power. Vol. 19, No. 12, December 1941, pp. 1027–1029.
[22] Mining and Industrial Magazine, Southern Africa, vol 29, November 1941, p. 331; reported in Bureau of Mines Mineral Trade Notes: Vol. 14, No. 2, February 20, 1942, pp 15–16.

The consumption of South African corundum in the United States has increased rapidly during the last few years. The material is crushed and sized, and the coarse grain products are sold to manufacturers of grinding wheels, especially snagging wheels, and the finer-grained products to optical lens grinders. The fine dust (minus-240-mesh) and the secondary materials mixed with glass and reduced in size after use by the optical instrument workers are sold to retail opticians.

With the issuance on February 10, 1942, of War Production Board General Preference Order M-89, corundum was made subject to full allocation. Under the order, corundum used in the manufacture of some civilian products may be curtailed, and suppliers will make deliveries only when specifically authorized by the Director of Industry Operations, War Production Board. The Director will periodically allocate corundum and specifically direct the manner and quantities in which deliveries shall be made. Future allocations may be made without regard to any preference ratings assigned to particular contracts or purchase orders, but they will be made to insure the filling of Government war orders.

Emery.—The production of emery in 1941 rose to 4,876 short tons valued at $42,484—the highest output since World War I when production including a small quantity of corundum, reached 10,422 tons in 1918. In 1941, as in recent years, all the output came from the Peekskill district in southeastern New York State (see fig. 7). Increased shipments were reported by the three producers mining emery in 1941, who also produced in 1940—DiRubbo & Ellis, the Howard Emery Corporation, and Joe DeLuca; in addition, Scalzo & Pisano operated in 1941 and sold their entire output through DeLuca. Mining is conducted by crude hand methods on account of the toughness of the ore, which occurs in veins of norite. Demand is increasing as new uses are being developed. Production at the DeLuca mine in January and February 1942 is said to have been three times that in the corresponding months of 1941.[23]

Emery sold or used by producers in the United States, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	320	$2,780	1940	1,046	$9,349
1938			1941	4,876	42,484
1939	765	6,828			

NATURAL CARBON ABRASIVES[24]

Abrasive or industrial diamonds.—The demand for abrasive or industrial diamonds in the United States is satisfied principally through the importation of black diamonds or carbonados (largely from Brazil) and diamonds for industrial use (chiefly from the Union of South Africa but with increasing importations from Brazil). Some diamond dust and bort also are imported, although usually in comparatively small and decreasing quantities in recent years. Imports of "glaziers' and engravers', unset, and miners' " diamonds (a classification comprising

[23] Rocks and Minerals, vol. 17, No. 3, March 1942, p. 107.
[24] See also chapter on Gem Stones in this volume.

mostly if not entirely diamonds for industrial use) in January–September 1941 continued at approximately the same high average monthly rate as in 1940 and totaled 2,911,117 carats valued at $7,415,133. The average value per carat in 1941 was $2.55, a continuation of the trend since 1929 toward lower values per carat, broken only in 1934 and 1940.

A comprehensive review of the diamond trade in 1940 in all countries of the world, dealing with both mining and cutting operations and treating in detail the South African trade and mining conditions for each of the main factors in the industry, was presented by Ball.[25] Discussion includes an excellent account of the industrial diamond situation and the elements contributing to the greatly augmented consumption of industrial stones in recent years.

A good description of the South African diamond mines, including methods of mining, processing of the "blue earth" to recover the stones, and a brief outline of the methods of cutting and the industrial uses, with several illuminating illustrations, was published.[26] A great amount of information about industrial diamonds, contributed by outstanding authorities in the various phases of the industry, was published in the early part of 1942.[27]

In addition to diamonds and synthetic and natural rubies and sapphires, a number of other hard and tough stones, such as garnet, chrysoberyl, spinel, zircon, topaz, rock crystal, and agate, are used as watch and chronometer jewels, as bearings for meters or other scientific instruments, and for timing instruments, such as mechanical fuses for bombs, switches, and microgears.[28] Details of the chief uses of the various stones are given, as well as a résumé of the shifts in use from one type to another with changing industrial conditions, with particular reference to Montana sapphires.

Stress was placed on the importance of diamond, corundum, emery, and various gem stones, such as synthetic rubies and sapphires and natural rubies, sapphires, and amethysts, used for jewel bearings in watches and in precision instruments of various types.[29] Jewel bearings, their relation to industrial precision instruments for both military and civilian use, and sources of supply of natural and synthetic material were discussed by Jensen.[30]

ARTIFICIAL ABRASIVES

Production of manufactured (artificial) abrasives in 1941 exceeded all previous records, the total quantity reported being 54 percent above 1940 and the value 52 percent above 1929, the previous record years for tonnage and value, respectively. Plants manufacturing aluminum oxide and silicon carbide (see fig. 7) in Canada and the United States operated at full capacity in 1941 and produced 44,962 short tons of silicon carbide valued at $3,325,928 and 147,759 short tons of aluminum oxide valued at $9,067,732—an increase of 36 percent over 1940

in tonnage of silicon carbide and 50 percent in tonnage of aluminum oxide. Although manufacturers of metallic abrasives (steel shot and grit) operated at only slightly above 60 percent of capacity, sales of these commodities in 1941 also set an all-time record, rising to 86,309 short tons or 73 percent above the former record (in 1940).

[1] Bureau of Mines not at liberty to publish data for United States separately.
[2] Production; includes material used for refractories and other nonabrasive uses.

Production of silicon carbide and aluminum oxide is concentrated chiefly in the Niagara Falls region of the United States and Canada, but some output of aluminum oxide comes from Quebec, Canada, and from Alabama. Producers of aluminum oxide in 1941 were requested to report separately the tonnage and value of "white—high-purity or special" aluminum oxide produced. These figures, not segregated heretofore from the total aluminum oxide output, were 22,659 short tons valued at $2,676,753. Estimates based upon percentages reported by producers indicate that 32 percent of the silicon carbide output in 1941 and 3 percent of the aluminum oxide production were consumed for refractory or nonabrasive purposes compared with 32 and 2 percent, respectively, in 1940.

Steel shot and grit are manufactured largely in northern Ohio and in Pittsburgh, Pa., but some comes from Michigan and New Hampshire. Two new plants producing metallic abrasives were reported in 1941—a second mill of the Cleveland Metal Abrasive Co. (Cleveland, Ohio), at Howell, Mich., and the Industrial Metal Abrasives Co., Jackson, Mich.

The physical properties and industrial uses in special refractories of abrasives, such as fused alumina, silicon carbide, and electrically fused magnesia, were discussed by Fisher.[31] Employment of these materials is desirable where operating temperatures are extremely high and high heat transfer is desired, where chemical erosion and mechanical abrasion are severe, and where contamination of the melt must be avoided.

MISCELLANEOUS MINERAL ABRASIVE MATERIALS

In addition to the natural and manufactured abrasive materials discussed, many other mineral substances have abrasive uses. Various oxides, including tin oxide, rouge, crocus, chromium oxide, magnesium oxide, and manganese oxide, are utilized as polishing agents. Finely ground as well as calcined clays, high-grade lime, talc, river silt, slate flour, whiting, feldspar, and other substances also are used as abrasives.

FOREIGN TRADE[32]

In the period January–September 1941 imported crude pumice virtually dropped out of the domestic market and "manufactured"-pumice imports ceased because of the war and the difficulties of transportation from Italy, heretofore by far the chief source of foreign pumice. Receipts of bort also declined sharply. The value of diamond dust, however, was greater than in the full year 1940, and average monthly imports of "glaziers' and engravers', unset, and miners'" diamonds in the first 9 months of 1941 were only slightly less than in the year 1940. Imports of emery ore (from Greece) ceased, although receipts of corundum ore during January–September 1941 were larger than in any full year since 1936.

The total value of exports of natural abrasive materials in the January–September period of 1941 rose about 17 percent compared with the full year 1940, in spite of a severe drop in exports of both grindstones and emery and corundum abrasive wheels. The value of "All other natural abrasives, whetstones, hones, etc." exported during January–September 1941, however, jumped to $1,716,054—42 percent above the entire year 1940 and higher than in any year since 1921.

SULFUR AND PYRITES

By Allan F. Matthews and A. W. Mitchell [1]

SUMMARY OUTLINE

GENERAL SUMMARY

Spurred by the call for immense quantities of war products and nutritious food, world production of sulfur reached the highest rate in its history during 1941. Sulfur flowed in unprecedented quantities from the Gulf coast mines—largest in the world—to the industries of the United Nations. In the other camp, the Axis countries found their sulfur sources ample, although supplies at consumption centers apparently were not adequate at all times. Italy's economic dependence on Germany was alleviated to some extent by a large exportable surplus of sulfur. Not only Italian sulfur but also pyrites from Scandinavia, Germany proper, Yugoslavia, Poland, and other Continental regions, augmented by increased recoveries from industrial gases, contributed to the Reich's sulfuric acid supply. The volcanoes that built the Japanese archipelago make it self-sufficient in sulfur. Spain, normally the most important source of pyrites, suffered a mining slump in 1941 and, aside from some exports to the United States and Great Britain, consumed most of its pyrites domestically.

In the United States production of both sulfur and pyrites broke all previous records during 1941, and shipments of sulfur from the mines were a third higher than ever before. Native sulfur produced in the United States through 1941 has totaled more than 50 million long tons; virtually the entire quantity has been mined since 1900. The principal trends in the sulfur and pyrites industries are shown in figures 1 and 2. Mine stocks of sulfur at the close of 1941 were sufficient to last over a year, even at the increased current rate of consumption. New acid-plant capacity totaling more than 1,000 tons a day of sulfuric acid (100-percent basis) went into operation in 1941, according to Chemical and Metallurgical Engineering, and additional capacity planned for 1942 amounts to some 1,700 tons daily. No priorities were imposed on sulfur, pyrites, or sulfuric acid by the Office of Production Management in 1941. Prices of these commodities were under the surveillance of the Office of Price Administration but remained steady without official action. Early in 1942

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

one of the largest American sulfur producers announced that there would be no rise in the base price of the mineral during the coming year. However, rerouting of domestic shipments from coastwise traffic to rail and inland waterway is certain to increase the delivered price.

[1] Bureau of Mines not at liberty to publish figures.
[2] Figures cover January to September, inclusive.
[3] Less than 1 ton.
[4] Revised figures.

A sound motion-picture film, The Story of Sulfur, available for exhibition to responsible organizations, was prepared in 1941 under the supervision of the Bureau of Mines in cooperation with one of the principal sulfur-producing companies. Duecker and Eddy,[2] in an excellent article, reviewed some of the influences of sulfur in the development of American industry. The tribunal that studied the effects of sulfurous gases from the smelter at Trail, British Columbia, reported its decision in 1941.[3]

SULFUR

DOMESTIC PRODUCTION

Production of crude sulfur in the United States in 1941 attained a new record of 3,139,253 long tons, a 15-percent gain over the 1940 output. Mine shipments in 1941, exceeding those of 1940 by 33 percent, were likewise the highest ever reported. The United States sulfur-production figures do not include 414 long tons in 1941 and 330 in 1940 of sulfur-bearing material containing 12 to 70 percent sulfur and mined in Colorado, Nevada, and Texas for agricultural purposes.

Sulfur produced and shipped in the United States, 1937–41

Year	Produced (long tons)	Shipped		Year	Produced (long tons)	Shipped	
		Long tons	Approximate value			Long tons	Approximate value
1937	2,741,970	2,466,512	$44,300,000	1940	2,732,088	2,558,742	$40,900,000
1938	2,393,408	1,628,847	27,300,000	1941	3,139,253	3,401,410	54,400,000
1939	2,090,979	2,233,817	35,500,000				

THE INDUSTRY IN 1941 BY STATES

Nearly 83 percent of the domestic sulfur output in 1941 was from Texas, 17 percent from Louisiana, and less than 1 percent from California. No sulfur was mined in Utah in 1941.

Sulfur produced in the United States, 1937–41, by States, in long tons

Year	Texas	Louisiana	Other States [1]	Total
1937	2,392,680	342,230	7,060	2,741,970
1938	2,060,845	328,405	4,158	2,393,408
1939	1,665,400	422,600	2,979	2,090,979
1940	2,212,839	512,935	6,314	2,732,088
1941	2,596,731	533,620	8,902	3,139,253
	10,928,495	2,139,790	29,413	13,097,698

[1] 1937–40: California and Utah; 1941: California.

California.—Two operators—Paul Barnes and the Pacific Sulphur Co., at Bigpine, Inyo County—supplied the 1941 output.

Louisiana.—In 1941, for the fifth successive year, production was confined to that of the Freeport Sulphur Co., at Grande Ecaille, Port Sulphur, Plaquemines Parish.

[2] Duecker, W. W., and Eddy, E. W., Sulfur's Role in Industry: Chem. Ind., vol. 50, No. 2, February 1942, pp. 174–182.

[3] Trail Smelter Arbitration Between the United States and Canada, Decision of the Tribunal, Reported March 11, 1941, U. S. Govt. Printing Office, 1941, 61 pp.

Texas.—The sulfur properties active in 1941 included those of the Duval Texas Sulphur Co. at Orchard Dome, Fort Bend County, and at Boling Dome, Boling, Wharton County; Freeport Sulphur Co. at Hoskins Mound, Brazoria County; Jefferson Lake Sulphur Co., Inc., at Clemens Dome, Brazoria County; and Texas Gulf Sulphur Co. at Boling Dome, Newgulf, Wharton County. Exploration for sulfur is being undertaken on Spindletop Dome, Jefferson County. The following table, compiled from information issued by the Texas State Comptroller's Office, shows the quarterly production of sulfur in Texas during 1941.

Sulfur produced in Texas in 1941, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co.	361,746	385,208	481,093	611,344	1,839,391
Freeport Sulphur Co.	85,545	93,470	93,365	99,200	371,580
Duval Texas Sulphur Co.	47,720	46,727	48,495	58,540	201,482
Jefferson Lake Sulphur Co., Inc.	52,675	51,979	46,123	33,501	184,278
	547,686	577,384	669,076	802,585	2,596,731

Utah.—Elemental sulfur has been produced from smelter gases since 1940 at Garfield, Salt Lake County, by the American Smelting & Refining Co. as a byproduct of copper operations. It was expected that the initial output would be 2 long tons a day. This quantity is not included in the figures showing total United States sulfur production.

Washington.—A sulfur deposit on Mount Adams, Yakima County, estimated in 1935 to contain 842,000 long tons of material averaging 46 percent sulfur, has been explored further by Pacific Sulphur Mines, Inc., which reports that larger quantities of sulfur are present.

RECOVERY AS BYPRODUCT

The treatment of copper and zinc ores yields large quantities of sulfur, which is recovered at the mills as pyrites concentrate or at the smelters as sulfuric acid. The production of pyrites concentrate is discussed in the Pyrites section of this chapter. In smelting copper and zinc concentrates, sulfur is driven off as sulfur dioxide gas, which is used in the manufacture of sulfuric acid at many smelters. Means of increasing the recovery of sulfur dioxide from smelter gases have been described by the Bureau of Mines.[4] The equivalent of about 180,000 long tons of sulfur was recovered as sulfuric acid annually from this source during the 5 years ended in 1941. Such sulfur is not included in the sulfur-production figures for the United States, but the following table shows the output of byproduct acid at both copper- and zinc-smelting plants. The acid reported is only that made from the sulfur content of sulfide ores but does include, for 1937 to 1938, inclusive, the relatively small quantity of acid made from pyrites concentrate in Wisconsin.

[4] Miller, Virgil, Bainbridge, R., and Ellison, R., Increasing the Concentration of Sulfur Dioxide in the Effluent Gases from Dwight-Lloyd Sintering Machines Treating Lead Products. Bureau of Mines Tech. Paper 624, 1941, 34 pp.

Byproduct sulfuric acid [1] *(expressed as 60° B.) produced at copper and zinc plants in the United States, 1937–41, in short tons*

	1937	1938	1939	1940	1941
Copper plants [1]	291,638	220,297	249,569	254,025	243,812
Zinc plants	542,356	466,879	528,872	586,912	672,177
	833,994	687,176	778,441	840,937	915,989

[1] Includes a small amount of sulfuric acid produced as a byproduct in the roasting of high-sulfide gold and silver concentrates.

Byproduct sulfur is also recovered from coke-oven gas, water gas, refinery-still gas, natural gas, and other fuel gases. A pictorial flow sheet of the recovery of sulfuric acid from waste oil-refinery sludges was published in 1941.[5] For a long time, hydrogen sulfide has been removed from manufactured gases by passing the gas through trays of iron hydroxide to form iron sulfide, known as spent oxide. This material has been used as a source of sulfur in Europe but not to any appreciable extent in the United States. During the last decade, however, the recovery of sulfur from fuel gases has been expanding in this country as a result of developments in various liquid-purification processes. Not all such processes are designed to permit recovery of sulfur as a byproduct, but those that do may be divided into two classes—those that recover elemental sulfur and those that give hydrogen sulfide as an end product. The latter have received increasing attention in recent years. Typically, processes that recover elemental sulfur operate on manufactured fuel gases, whereas those that recover hydrogen sulfide are applied to refinery-still gas and natural gas, and usually these gases are under high pressure. Investigation has indicated, however, that the phenolate processes, at least, are adapted to the removal and recovery of sulfur from low-pressure, low-sulfur gases, such as coke-oven gas.

Most of the elemental sulfur recovered from gas purification results from operations using the Thylox process; relatively minor quantities are recovered from the Ferrox and Nickel processes. Production in 1941 (reduced to 100 percent sulfur) totaled 5,493 long tons; 4,866 tons valued at $136,000 were shipped. Output came from Illinois, Maryland, Massachusetts, Missouri, New Jersey, New York, Washington, West Virginia, and Wisconsin; Massachusetts and New York were the largest producers. The sulfur is produced and marketed either as a paste containing 37 to 50 percent sulfur or as a dried, relatively pure sulfur. The fine particle size of this sulfur makes it valuable as a fungicide and insecticide for agricultural purposes. Of the 1941 shipments (reduced to 100 percent sulfur), 34 percent was in the form of paste and the remainder was dried sulfur.

Most of the hydrogen sulfide recovered as a byproduct from fuel gases is either converted to sulfuric acid or burned as fuel. Recovery is by the phenolate, phosphate, and Girbotol processes. In 1941 the output of hydrogen sulfide extracted from fuel gases (and, for the most part, converted to sulfuric acid) was equivalent to 21,197 long tons of sulfur. Most of this was recovered by petroleum refineries in California and the remainder by companies in Illinois, New Jersey, Pennsylvania, and Texas.

[5] Chemical and Metallurgical Engineering, vol. 48, No. 5, May 1941, pp. 144–147.

The figures on byproduct yield of sulfur from gas purification are not included in the sulfur-production figures for the United States.

The reactions of sulfur dioxide from waste gases with oxide ores and common salt in the direct production of anhydrous sulfates and chlorides were studied recently.[6]

STOCKS

As shipments exceeded production in 1941, stocks at the mines decreased 300,000 long tons during the year and on December 31 amounted to 3,900,000 tons.

PRICE

The price of crude sulfur held to the level of recent years and was quoted by trade journals throughout 1941 at $16 a long ton, f. o. b. mines. Sulfuric acid, 66° B., continued to be listed at $16.50 a short ton.

CONSUMPTION

Apparent domestic consumption of sulfur in recent years is shown in the following table, although data for 1941 are incomplete as the figures for imports and exports cover only the first 9 months of the year.

Apparent consumption of sulfur in the United States, 1937–41, in long tons

	1937	1938	1939	1940	1941
Shipments	2,466,512	1,628,847	2,233,817	2,558,742	3,401,410
Imports	628	2,603	13,976	27,845	[1] 20,954
	2,467,140	1,631,450	2,247,793	2,586,587	([2])
Exports:					
Crude	675,297	579,107	627,819	746,468	[1] 474,551
Refined	13,533	12,707	25,005	19,745	[1] 24,683
	688,830	591,814	652,824	766,213	[1] 499,234
Apparent consumption	1,778,310	1,039,636	1,594,969	1,820,374	([2])

[1] Figures cover January to September, inclusive.
[2] Figures not available.

The consumption of sulfur in various industries from 1937 through 1941 has been estimated by Chemical and Metallurgical Engineering as follows:

Sulfur consumed in the United States, 1937–41, by uses, in long tons [1]

Use	1937 [1]	1938 [1]	1939	1940	1941
Chemicals	777,000	484,000	695,000	800,000	[2] 1,060,000
Fertilizer and insecticides	415,000	220,000	370,000	410,000	450,000
Pulp and paper	302,000	174,000	240,000	320,000	360,000
Explosives	68,000	50,000	64,000	74,000	[2] 83,000
Dyes and coal-tar products	49,000	40,000	46,000	51,000	65,000
Rubber	37,000	29,000	43,000	47,000	55,000
Paint and varnish	64,000	50,000	49,000	54,000	65,000
Food products	6,000	5,500	6,000	6,000	6,000
Miscellaneous	82,000	47,500	82,000	86,000	95,000
	1,800,000	1,100,000	1,595,000	1,848,000	2,239,000

[1] Figures for 1937 and 1938 are not truly representative of consumption but rather of shipments to these specified industries. In 1938 consumers carried over large stocks from 1937, so that actual consumption in 1937 was less than the figures indicate and consumption in 1938 was larger than the total shown.
[2] To avoid disclosing estimated consumption of sulfur in direct defense applications, such as military explosives, sulfur so used in 1941 is included under "Chemicals."

[6] Johnstone, H. F., and Darbyshire, R. W., Sulfur Dioxide as a Raw Material: Ind. and Eng. Chem., Ind. ed., vol. 34, No. 3, March 1942, pp. 280–286.

Most of the sulfur and pyrites are consumed as sulfuric acid—one of the most universally required of heavy chemicals. Production of sulfuric acid (50° B. basis) in the United States, as estimated by Chemical and Metallurgical Engineering, was 10,944,000 short tons in 1941 compared with 9,174,000 tons in 1940.[7] Consumption of sulfuric acid in 1941 increased 20 percent over 1940. The largest consumer—the fertilizer industry—used 11 percent more acid than in 1940 as a result of increased demand for superphosphate. It is estimated that this industry will need about 2,980,000 tons of acid in 1942, an increase of approximately 18 percent over 1941.[8] The iron and steel industry needed 21 percent more sulfuric acid in 1941 than in 1940, primarily for pickling purposes and the recovery of nitrogen as ammonium sulfate in the coking process. Petroleum refineries increased their acid consumption 11 percent during 1941, partly because of the augmented call for high-octane aviation gasoline. The tremendous increase in demand for fuming sulfuric acid (oleum), little used except for explosives, was met by erecting auxiliary equipment at existing acid plants. It may be significant that a process has been developed for the continuous nitration of benzene without the use of sulfuric acid.[9]

Chemical and Metallurgical Engineering has estimated the consumption of sulfuric acid, by industries, from 1937 through 1941 as follows:

Sulfuric acid (expressed as 50° B.) consumed in the United States, 1937–41, by industries, in short tons

Industry	1937	1938	1939	1940	1941
Fertilizer	2,230,000	1,900,000	1,970,000	2,260,000	2,500,000
Petroleum refining	1,100,000	1,100,000	1,210,000	1,260,000	1,400,000
Chemicals	1,020,000	800,000	975,000	1,120,000	[1] 1,790,000
Coal products	865,000	585,000	740,000	900,000	940,000
Iron and steel	1,100,000	590,000	980,000	1,200,000	1,450,000
Other metallurgical	625,000	350,000	570,000	640,000	800,000
Paints and pigments	525,000	430,000	520,000	580,000	700,000
Explosives	180,000	140,000	160,000	170,000	[1] 190,000
Rayon and cellulose film	380,000	320,000	405,000	470,000	555,000
Textiles	112,000	90,000	116,000	125,000	165,000
Miscellaneous	450,000	355,000	384,000	460,000	550,000
	8,587,000	6,660,000	8,030,000	9,185,000	11,040,000

[1] To avoid disclosing estimated consumption of acid in direct defense applications, such as military explosives, acid so used in 1941 is included under "Chemicals."

A nonelectrolytic method of producing chlorine from common salt and sulfur was announced in 1941.[10] The manufacture of sulfur pipe for corrosive liquids was described by Bencowitz.[11] A pictorial flow sheet of the production of sulfite pulp was published.[12]

FOREIGN TRADE

Sulfur imports in the first 9 months of 1941 were 20,954 long tons, including 20,937 tons from Canada, 16 tons from the United Kingdom, and 1 ton from Japan. The Canadian material is elemental sulfur

[12] Chemical and Metallurgical Engineering, vol. 48, No. 8, August 1941, pp. 106–109.

recovered from smelter gases. Imports of sulfuric acid in the same period totaled 2,292 short tons—74 percent from Canada and the remainder from Mexico.

Distribution of exports in 1941 by countries of destination is not available for publication; figures for 1939 and 1940 are shown in the preceding chapter of this series. Exports of sulfuric acid in the first 9 months of 1941 totaled 9,937 short tons; 42 percent was oleum. The materials allocated to Latin America by the Office of Production Management for the first 3 months of 1942 included 1,000 tons of sulfuric acid.

Sulfur imported into and exported from the United States, 1937–41

Year	Imports				Exports

[1] Less than 1 ton.

WORLD PRODUCTION

World production of sulfur in 1940, including elemental sulfur recovered in the treatment of pyrites and as a byproduct from the treatment of industrial gases, is estimated at 3,600,000 long tons.

World production of native sulfur, 1936–41, by countries, in long tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1936	1937	1938	1939	1940	1941

[1] Native sulfur is believed to be produced also in Argentina, China, Cuba, India, Iran, and U. S. S. R., but the quantity is unknown.
[2] In addition, the following quantities of sulfur rock (40–80 percent sulfur) are reported: 1936, 11,612 tons; 1937, 1,050 tons.
[3] Data not available.
[4] In addition, the following quantities of sulfur rock are reported: 1936, 20,743 tons; 1937, 19,793 tons; 1938, 16,545 tons. Similar data are not available for later years.
[5] Crude sulfur.
[6] Refined sulfur, exclusive of that made from imported crude sulfur.

Australia.—Production of elemental sulfur from byproduct pyrites is being considered.

Bolivia.—Most of the current exports go to Argentina. A deposit at Napa, Department of Potosi, is reported to contain 5,000,000 tons of material averaging 65 percent sulfur.

Canada.—Elemental sulfur is produced from base-metal smelter gases at Trail, British Columbia, and the feasibility of a similar operation at Montreal East, Quebec, is to be tested by a pilot plant now under construction. Canada exported 20,937 long tons of this byproduct sulfur to the United States in the first 9 months of 1941. The Aldermac project for the production of elemental sulfur from pyrites is still a possibility. Sulfuric acid is manufactured from smelter gases at Trail, British Columbia, and Copper Cliff, Ontario. Seven acid plants manufactured a total of 283,618 metric tons of sulfuric acid (66° B. basis) in 1940.[13]

Chile.—Exports of sulfur totaled 21,371 long tons in 1941 compared with 27,637 tons in 1940. A subsidy has been granted to a Chilean company that will supply 300 long tons of refined sulfur monthly from a deposit in the Province of Arica.[14]

China.—Production of sulfur in Unoccupied China is estimated at 3,540 long tons in 1940.

Costa Rica.—Five deposits in the foothills of volcanoes in the Province of Guanacaste are said to analyze 85 to 95 percent sulfur.

Cuba.—An apparently small underwater sulfur deposit is being worked near Punto Carabela Chica, Province of Pinar del Rio.

Germany.—The Reich has access to large supplies of sulfur from Italy. Furthermore, production of elemental sulfur has been increased by new processes for recovering sulfur from coke-oven and coal-distillation gases at very low concentrations. German sulfuric acid output was reported at 2,800,000 metric tons in 1939.[15]

India, British.—Sulfur operations in the vicinity of the volcanic mountain of Koh-i-Sultan, near Nok Kundi, Baluchistan, were reported to have begun in 1941 with an expected output, for at least a short time, of 60,000 long tons of crude ore annually.

Iran.—Sulfur production in 1939 was reported at approximately 1,000 long tons.

Japan.—The Matsuo mine, Province of Rikuchu, which normally supplies about 25 percent of Japan's sulfur output and which was wrecked by a fire in November 1939, was still idle during most of 1941 but was expected to be in operation again by the beginning of 1942. Sulfur was put under allocation on June 1, 1941, by the Japan Sulfur Control Association. Owing to a shortage of power and to insufficient sulfur supplies, the 1940 production of sulfuric acid is said to have declined to 70 percent of capacity, carbon bisulfide to 43 percent, sodium sulfide to 65 percent, and ammonium sulfate to 79 percent. Plans were instituted in 1941 to raise Japanese sulfuric acid production to 4,000,000 metric tons annually, which would represent a substantial advance over the 1938 output of approximately 2,800,000 tons. The contact process, according to Chemical Age,[16] represented 30 percent of the sulfuric acid capacity in 1939. Exports during the first 9

[16] Chemical Age, vol. 44, No. 1129, February 15, 1941, p. 100.

months of 1940 included 120 long tons of sulfur and 132 metric tons of sulfuric acid.

Mexico.[17]—A plant has been completed for refining sulfur mined in the State of San Luis Potosi. Sulfuric acid is produced from smelter gases in northern Coahuila.

Norway.—Elemental sulfur is produced from pyrites at the Thamshavn plant of the Orkla Metal Co. An agreement to ship part of the output to Sweden during 1941 was extended to cover 1942.

Portugal.—Production of elemental sulfur from pyrites totaled 9,915 long tons in 1940.

Sweden.—Elemental sulfur is produced from smelter gases at Ronskar, northern Sweden, by the Boliden Co.

United Kingdom.—Control of Sulfuric Acid (No. 2) Order, 1940, Direction 3, effective May 9, 1941, fixed the base price at 27s. a ton for 77-percent acid and 34s. 4d. for 98-percent acid.

PYRITES

DOMESTIC PRODUCTION

Pyrites production in the United States in 1941 exceeded that in 1940 by 5 percent and reached a new record. Ninety-five percent of the output was fines and the remainder lump, the former being principally flotation concentrates.

Pyrites (ores and concentrates) produced in the United States, 1937–41

Year	Quantity		Value	Year	Quantity		Value
	Gross weight (long tons)	Sulfur content (percent)			Gross weight (long tons)	Sulfur content (percent)	
1937	584,166	39.7	$1,777,787	1940 [1]	626,640	41.8	$1,920,000
1938	555,629	39.4	1,685,766	1941	659,498	41.8	2,035,000
1939 [1]	519,497	42.3	1,560,000				

[1] Revised figures.

Producers consumed 443,983 long tons and sold 207,504 tons in 1941 compared with revised figures of 422,545 and 206,867 tons, respectively, in 1940. Domestic pyrites mined in 1941 had an average sulfur content of 42 percent and an average value of $3.09 a long ton, f. o. b. mines. Spanish pyrites, minimum 48 percent sulfur, continued to be quoted nominally at 12 cents per long-ton unit of sulfur, c. i. f. U. S. ports, throughout 1941.

THE INDUSTRY IN 1941 BY STATES

California.—The Mountain Copper Co. was the only producer of pyrites in California in 1941; output came from the Hornet mine in Shasta County.

Colorado.—The output of pyrites in Colorado in 1941 totaled 11,774 long tons and was produced by Minnesota Mines, Inc., Clear Creek County, and by John Andrew from a mill tailings dump in Lake County.

[17] Chemical and Engineering News, vol. 20, No. 4, February 25, 1942, p. 281.

Illinois.—From its coal-cleaning operations at the Atkinson mine in Henry County the Midland Electric Coal Corporation produced and shipped 12,026 long tons of pyrites (coal brasses) containing 46 percent sulfur in 1941.

Indiana.—The Snow Hill Coal Corporation produced pyrites (coal brasses) at its Talleydale mine in Vigo County in 1941.

Kansas.—The Mineral Products Co. produced 3,902 long tons of pyrites (coal brasses) containing 44 percent sulfur at West Mineral, Cherokee County, in 1941.

Missouri.—No pyrites production was reported from Missouri in 1941.

Montana.—The pyrites produced in Montana in 1941 came from the Anaconda Copper Mining Co. at Anaconda, where it is recovered as a flotation concentrate in copper operations.

New York.—In 1941 New York produced 63,958 long tons of pyrites containing 49 percent sulfur.

Pennsylvania.—Pyrites concentrates were produced in 1941 by the Bethlehem Steel Co. at the Cornwall mine, Lebanon County.

Tennessee.—The output of the Tennessee Copper Co., Ducktown Basin, Polk County, enabled Tennessee to retain its rank as the principal producer of pyrites in 1941. The product, a flotation concentrate, does not enter the market but is consumed by the company in the manufacture of sulfuric acid.

Virginia.—The General Chemical Co. has been obtaining the only pyrites mined in Virginia in recent years from the Gossan mine at Cliffview, Carroll County. The output is concentrated by air tables for the manufacture of sulfuric acid in the company plant at Pulaski.

Wisconsin.—The one company reporting production of pyrites in Wisconsin in 1941 was the Vinegar Hill Zinc Co., which recovers pyrites by flotation from ores mined in the Platteville district, Grant County.

FOREIGN TRADE

Imports of pyrites, by countries of origin, in recent years are shown in the following table. Spanish shipments, normally the principal foreign source, dwindled to 21 percent of the imports in the first three quarters of 1941, while Canada supplied virtually all the rest.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1937–41, by countries

Country	1937		1938		1939		1940		1941 (Jan.-Sept.)	
	Long tons	Value	Long tons	Value	Long tons	Value	Long tons	Value	Long tons	Value
Canada	20,558	$74,946	30,064	$135,659	176,804	$470,336	81,157	$560,476	177,030	$855,533
Greece					22,800	106,271				
Mexico	549	1,473	202	522			203	719	125	525
Portugal	21,725	109,395								
Spain	481,598	1,158,671	303,968	709,983	282,732	738,439	325,644	790,172	47,109	122,671
	524,430	1,344,485	334,234	846,164	482,336	1,315,046	407,004	1,351,367	224,264	978,729

In keeping with the changing source of imported pyrites, shipments to Philadelphia, New York, and Baltimore slumped heavily in the first 9 months of 1941, and those to Buffalo more than doubled.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1937–41, by customs districts, in long tons

Customs district	1937	1938	1939	1940	1941 (Jan.–Sept.)
Buffalo	584	5,130	21,940	80,076	168,984

WORLD PRODUCTION

Recent figures on the pyrites output of many of the countries are not obtainable, but annual world production has been approximating 10,000,000 metric tons containing about 4,300,000 tons of sulfur.

World production of pyrites (including cupreous pyrites), 1938–40, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1938		1939		1940

[1] In addition to countries listed, Brazil, China, Chosen, Czechoslovakia, Eire, India, Japan, and U. S. S. R. produced pyrites, but production data are not available.
[2] Data not available.
[3] Production data (gross weight) not heretofore available for 1936 and 1937 are 1,739,793 and 2,277,428 tons, respectively. Average sulfur content of Spanish pyrites was 42 percent in 1931, the latest year for which such information is available.
[4] Estimated.
[5] Revised figures.

Australia.—The copper mines at Mount Lyell, Tasmania, have a daily output of 145 metric tons of pyrites concentrates containing 51 percent sulfur.[18] Proposals for expansion of Australian pyrites production are being considered.

Brazil.—A mine at Rio Claro, State of Rio de Janeiro, has a daily output of 2 metric tons of pyrites averaging 43 percent sulfur. Production of pyrites in Parana and also as a byproduct of coal mining is contemplated.

Canada.—Pyrites concentrates are produced as an accessory to copper at the Aldermac and Noranda mines in Quebec and the Britannia mine in British Columbia. Output from Delestre Township, Quebec, is anticipated in 1942. Noranda Mines, Ltd., is now recovering essentially all of its pyrites concentrates, and drier equipment ordered in 1941 was expected to increase the capacity to about 450 metric tons daily.[19] Canada exported 179,871 metric tons of pyrites to the United States during the first 9 months of 1941. A second paper mill in the Dominion has turned from imported sulfur to Canadian pyrites as a source of sulfur dioxide. Thousands of tons of pyrites cinder containing about 50 percent iron were shipped in 1941 from Ontario to the Republic Steel Corporation plant at Buffalo, N. Y.

Cyprus.—Production declined approximately 50 percent to 257,000 metric tons in 1940 and virtually ceased in 1941. Exports during the first 5 months of 1941 were only about 5,000 metric tons.

Czechoslovakia.—Production of iron pyrites in the Province of Slovakia, according to the German press, was 11,000 metric tons in 1941 and 14,000 tons in 1940 compared with 10,000 tons in 1939 and 18,000 tons in 1937.[20]

Eire.—Iron pyrites mining has begun in County Wicklow for production of sulfuric acid for fertilizer manufacture.

India, British.—Some pyrites is mined near Simla. A growing demand for sulfuric acid and the success of a pilot-plant extraction of elemental sulfur from pyrites may stimulate larger-scale exploitation of Indian pyrites.[21]

Norway.—New pyrites deposits were reported discovered in Norway in 1941. Sulfur and pyrites valued at 5,000,000 kroner (about $1,200,000) are to be exported to Sweden in 1942 in continuation of a previous trade agreement.

Portugal.—Production of pyrites was 372,506 metric tons in 1940 compared with 502,311 tons in 1939.[22] Exports were 179,423 tons in 1940 and 436,048 tons in 1939, going principally to France, the United Kingdom, and Belgium.

Spain.—Spanish pyrites production during the first 10 months of 1941 was 381,778 metric tons.[23] Water-borne shipments in 1940 were unofficially reported as 957,716 tons. The sharp decline in output is attributed primarily to limitations on available cargo space but also to lack of dynamite, coal, and equipment and loss of Continental markets. The Ministry of Industry in 1941 issued a decree, effective

toward the end of the year, ordering cupriferous pyrites to be roasted within the country to recover the copper for the manufacture of copper sulfate. A plant is being built at Valencia for yearly extraction of 2,250 metric tons of copper, 71,500 tons of iron, and 3,750 tons of sodium sulfate from cupriferous pyrites.[24] Of the current Spanish pyrites output, about one-third is going to the United States and an occasional cargo to England; the bulk of the remainder is consumed domestically.[25] Despite rumors to the contrary, apparently little or none is reaching Germany.

Sweden.—Test drillings have revealed new deposits of cupriferous pyrites in the Kuorbevaro district, Department of Västerbotten.

Union of South Africa.—Production was 16,118 metric tons in the first half of 1941 compared with 18,858 tons in the corresponding period of 1940.

United Kingdom.—Marcasite is produced as a byproduct in coal mining.

Yugoslavia.—Trepca Mines, Ltd., reported that, in the 4 months from November 1940 to February 1941, 247,291 metric tons of ore were milled, yielding 16,971 tons of pyrites in addition to lead, zinc, and copper concentrates.[26] The mines were undamaged when the Germans took them over in April 1941, but a shortage of workers is said to have hindered subsequent operations to some extent.

PHOSPHATE ROCK

By Bertrand L. Johnson and K. G. Warner

SUMMARY OUTLINE

GENERAL CONDITIONS

Never before was so much domestic phosphate rock marketed in a single year as in 1941. The quantity sold or used by producers exceeded the 4,103,982 long tons sold or used during the abnormal post-war boom year 1920 by over one-half million tons (see fig. 1). Shipments of phosphate rock from American mines in 1941 totaled 4,668,312 long tons [1] valued at $15,587,738, an increase over 1940 of nearly 700, 000 tons (17 percent) and of 3½ million dollars (26 percent). Mined production in 1941—4, 920, 843 tons, 21 percent above the 1940 figures—likewise broke all previous records. Exports for the first 9 months of the year, the only period for which figures can be published, were much greater (9 percent in quantity and 20 percent in value) than for all 12 months of 1940. No imports of phosphate rock or apatite were recorded in 1941.

Reports published in 1941 covering the phosphate-rock industry in general include papers by Jacob, McCord, Logue, and the Bureau of the Census.[2]

General scientific papers published include those by Mansfield,[3] Tremearne and Jacob,[4] Jacob and Ross,[5] Frondel,[6] Fahey and Tunell,[7] and Rader and Hill.[8]

[1] In addition to this tonnage, a small quantity of phosphate rock was mined and sold in Utah during 1941. The Bureau of Mines is not at liberty to publish the Utah output separately; therefore, it is not included in any of the figures in this chapter.

1 Figures not available. 2 Includes sintered matrix. 3 Virginia included with Tennessee.
4 Market value (or price) at port and time of exportation to the United States.
5 1940: Excludes sintered matrix, which is included under "Other phosphate materials"; 1941: Includes sintered matrix.
6 Value at port of exportation.
7 Figures cover January to September, inclusive.
8 Quantity sold or used by producers plus imports minus exports.
9 Figures not available for publication.
10 Includes brown-rock matrix of sinter grade and sintered brown rock.

PRODUCTION

Phosphate rock was mined in 1941 in Florida, Tennessee, Idaho, Montana, and Utah, and apatite was recovered from apatite-ilmenite ore in central Virginia. Total mine production reached about 5 million tons (4,920,843 long tons), nearly two-thirds of a million tons more than the previous all-time record of 4,261,416 tons reached in 1937. Production increased in Florida, Tennessee, and the Western States, and the mined production in each attained an all-time high.

Phosphate rock mined in the United States, 1932-41, by States, in long tons

Year	Florida	Tennessee [1]	Western States	United States	Year	Florida	Tennessee [1]	Western States	United States
1932	1,500,891	152,533	44,724	1,698,148	1937	3,179,588	942,158	139,670	4,261,416
1933	2,039,531	296,441	23,663	2,359,635	1938	2,722,927	[2] 999,551	137,998	3,860,476
1934	2,464,969	394,311	38,958	2,898,238	1939	2,791,360	1,057,570	139,040	3,987,970
1935	2,598,337	493,501	67,490	3,159,328	1940	2,782,956	1,120,551	164,570	4,068,077
1936	2,645,819	737,866	79,152	3,462,837	1941	3,417,900	1,301,067	201,876	4,920,843

1 Includes small quantity of apatite from Virginia.
2 Includes also small quantity of phosphate rock from South Carolina.

SALES

The quantity of phosphate rock sold or used by producers in 1941 (4,688,312 long tons) topped that in 1940 by over two-thirds of a million tons (17 percent) and the previous all-time high of 1920 (4,103,982 tons) by more than one-half million tons (see fig. 1). The total value in 1941 was 26 percent greater than the total in 1940; however, it was nearly 10 million dollars less than the 1920 peak, which was caused by the high average value ($6.11) of sales during the 1920 boom. In 1941 the average value of total sales was only $3.32 a ton, slightly higher than in 1940 but still in consonance with the slight downtrend of average values in recent years.

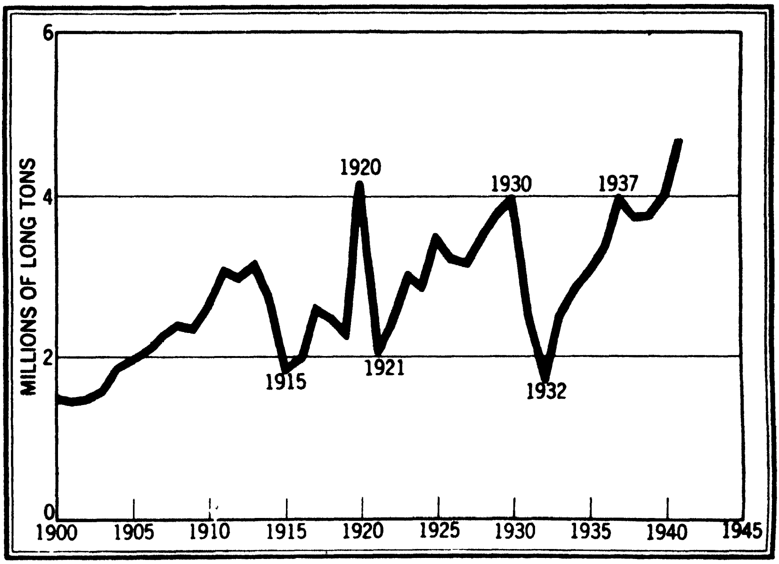

Figure 1.—Marketed production of domestic phosphate rock, 1900–1941.

Phosphate rock sold or used by producers in the United States, 1937–41

Year	Long tons	Value at mines: Total	Value at mines: Average	Year	Long tons	Value at mines: Total	Value at mines: Average
1937	3,956,189	$12,975,268	$3.28	1940	4,002,700	$12,334,662	$3.08
1938	3,739,238	12,952,143	3.46	1941	4,688,312	15,587,738	3.32
1939	3,757,067	12,294,042	3.27				

DISTRIBUTION OF SALES

Shipments of domestic phosphate rock in recent years have fallen largely into two distinct groups according to grade—one below 60 percent B. P. L. (bone phosphate of lime) and the other containing 68 percent B. P. L. and higher grades. In 1941 the gap between these two groups became more distinct; larger quantities of the lower grade, much less of the 60- to 66-percent grade, and considerably less of the

68 basis, 66 minimum grade were sold. Ninety-one percent of the sales of phosphate rock in 1941 were, however, still of the higher grades, mostly between 70 and 77. Only 60 percent of the total sales of domestic phosphate rock sold or used by producers for consumption in the United States appears to have gone into the manufacture of superphosphates, although the quantity so consumed was much larger in 1941 than in 1940. The use of phosphate rock in chemicals and for direct application to soils increased.

The following table, showing distribution of phosphate rock sold or used by producers by grades, uses, and classes of consumers, was compiled from reports to the Bureau of Mines by domestic producing companies.

Phosphate rock sold or used by producers in the United States, 1940–41, by grades, uses, and classes of consumers

	1940			1941		
	Quantity		Value	Quantity		Value

[1] Bone phosphate of lime.
[2] Figures not available.
[3] Less than 0.5 percent.
[4] Includes grades of B. P. L. content between 69 and 72.9, 72–73, 73, 73.8, 74.8, 76, 76.9, and above 85 percent; also ground phosphate rock and dust, B. P. L. content not known.
[5] Includes some calcined phosphate and phosphatic material used in pig iron blast furnaces, in manufacture of concentrated fertilizers, and in minor uses not specified.
[6] As reported to Bureau of Mines by domestic producers.

CONSUMPTION

The annual consumption of phosphate rock in the United States for 1867–1940 (data for 1941 not available for publication) is graphed in the accompanying diagram (fig. 2).

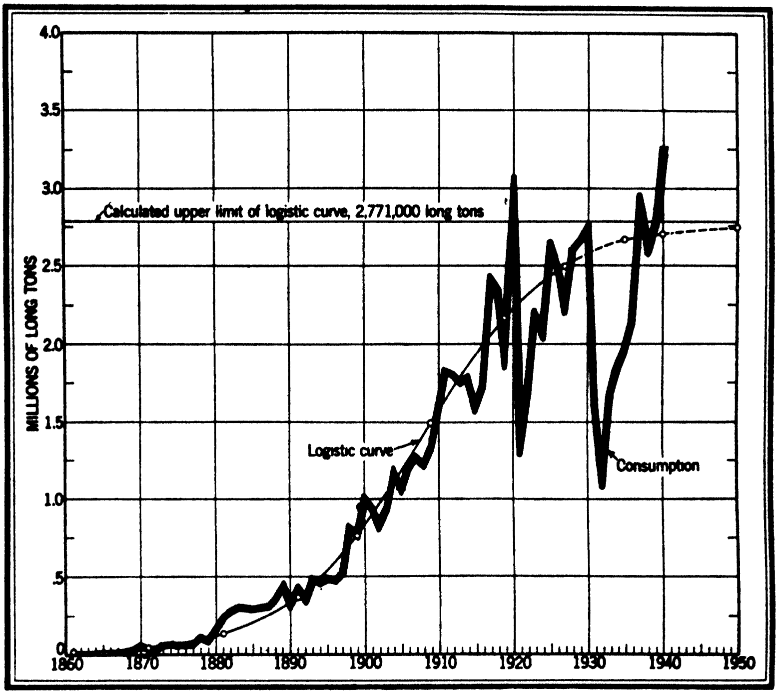

FIGURE 2.—Consumption of phosphate rock in the United States, 1867–1940.

PRICES

Trade-journal (Oil, Paint and Drug Reporter) quotations for the several grades of phosphate rock increased irregularly during the year, changes in one grade or another occurring in March, August, and September. The total advances ranged from 5 to over 38 percent. In December, a new method of stating grades, with lower ranges, was instituted; the prices, however, remained the same as the higher quotations of the period immediately preceding. The various changes in price quotations and grades throughout 1941 are shown in the following table.

The antitrust suit, originally against 102 defendants—2 trade associations, 64 fertilizer companies, and 36 officials of the defendant corporations—charged with violation of the Sherman Act, was terminated March 24, 1942, in the Federal District Court of the Middle District of North Carolina at Winston-Salem. The defendants, except 7 as to whom the case was nolle-prossed, entered pleas of nolo contendere. In lieu of trial, informal hearings were held March 16 to 24, 1942, for the information of the judge. Judgment was rendered March 24, 1942. Fines are reported to have been imposed on 63 corporations and 31 individuals. The indictment contained

two counts, charging price fixing and suppression of competition, and in most instances fines are stated to have been imposed on both counts.[9]

Prices per long ton of Florida and Tennessee phosphate rock, bulk f. o. b. mine, in 1941 [1]

REVIEW BY STATES

Florida.—Total shipments of phosphate rock from Florida were 18 percent greater in quantity and nearly 2½ million dollars in value in 1941 than in 1940, the average value of the shipments increasing from $2.72 in 1940 to $3.04 in 1941. Land-pebble shipments, which constituted 97 percent of all Florida phosphate-rock sales, likewise showed an 18-percent increase in quantity and more than a 2-million-dollar increase in value; the average value increased from $2.71 to $3.02. Soft-rock and hard-rock sales also increased. Soft-rock sales in 1941 were 14 percent greater in quantity and 29 percent in value than in 1940; hard-rock sales nearly doubled in quantity and more than doubled in value but still were far short of the 1939 figures. The average value reported for hard rock increased from $4.49 a ton in 1940 to $5.54 in 1941, the highest figure for several years. Hard rock-mining operations were conducted jointly by C. and J. Camp and J. Buttgenbach & Co. Operations started in October 1941 in sec. 22, where a preliminary washer feeds to the finishing washer at Felicia, 3 miles from Hernando. Shipments before October were made from stocks at the mines and at Fernandina. The other hard rock-operating company, Dunnellon Phosphate Mining Co., did

[1] Includes material from waste-pond operations.
[2] Includes sintered matrix.

The International Minerals & Chemical Corporation (formerly the International Agricultural Corporation) began operations on a new mine and plant to produce phosphate rock from other portions of its Florida reserves, owing to depletion of areas now being mined near Mulberry.

Cash [10] presents the data on accident experience of the pebble-phosphate industry in Florida for 1939 and 1940.

The Southern Phosphate Corporation in 1941 built an agglomerate tabling plant of 36 Deister-Overstrom tables at its Pauway mine to treat washer tailings from previous mining operations. Jones [11] has prepared a detailed, illustrated description of this plant. Edwards' [12] survey of electrical distribution and power applications at the Southern Phosphate Corporation mines and plants was published late in 1941.

The American Agricultural Chemical Co. is reported to have added dry mixing to its sulfuric acid and superphosphate operations at Pierce in 1941, so that it now has a complete fertilizer plant at that place. Its No. 1 recovery unit at Alderman Station is described in a recent report.[13]

The American Cyanamid Co. is reported to have built a new drying plant with a capacity of 150 tons per hour of wet phosphate rock.

Three papers by Taylor [14] on the land-pebble phosphate-rock deposits of Florida and the operations in that area have appeared in recent months.

Tennessee.—The tonnage of phosphate rock sold or used by Tennessee producers (plus a small quantity of apatite from Virginia) aggregated 1,120,358 long tons, exceeding the previous all-time high of 1940 by 13 percent and passing 1 million tons for the first time. The total value of shipments exceeded 4½ million dollars. All shipments from Tennessee were brown rock. Total stocks in the hands of producers at the close of 1941 were somewhat larger than on December 31, 1940, being a little over one-quarter million tons in each of the 2 years.

Tennessee phosphate rock (including sintered matrix) sold or used by producers, 1937–41

[1] Separate figures for brown rock and blue rock cannot be given without disclosing confidential data regarding blue-rock production.

Late in 1940 Whitlatch [15] presented a paper on the current and past estimates of phosphate reserves in Tennessee; he critically examined the data available and gave supplementary information on Tennessee reserves, repeating the conclusions given in a previous paper (see Minerals Yearbook, 1940, Review of 1939, p. 1309). In concluding this paper he states that—

> The history of reserve estimates clearly indicates the tendency of past investigators to underestimate the phosphate reserves, chiefly because of failure to properly evaluate future technologic advances and trade trends, which have had the effect of amplifying reserves. Although the latest (1938 and 1940) reserve estimates have endeavored to recognize such factors and have, in consequence, established record-breaking figures, the writer must conclude that probably within 10 to 25 years even these figures will be obsolete. Phosphate mining undoubtedly will continue in Tennessee long after the exhaustion of grades now included in reserve tonnages, and as these grades are exhausted, new means of recovery for still lower grades will be devised, and reserve estimates will be accordingly amplified.

Six private companies continued to supply by far the major part of the phosphate rock produced in Tennessee—the Armour Fertilizer Works, Charleston Mining Co., Federal Chemical Co., Hoover & Mason Phosphate Co., International Minerals & Chemical Corporation (formerly the International Agricultural Corporation), and Monsanto Chemical Co. Few changes have been reported in their operations. The Hoover & Mason Phosphate Co., however, made radical changes in the intake end of its washing plant by removing the high towers and blast-furnace skips ahead of the washing and drying plants. Both have been replaced by belt conveyors from ground storage. The grinding- and bagging-plant capacity was also increased.

The phosphate-rock matrix-nodulizing plant completed at the Mount Pleasant (Tenn.) plant of the Charleston Mining Co. in 1938,

[15] Whitlatch, G. I., Current and Past Estimates of Phosphate Reserves in Tennessee: Jour. Tennessee Acad. Science, vol. 16, No. 4, 1941, pp. 310–325.

with added improvements in 1939 and 1940, is described in a recent illustrated article by Nordberg.[16]

The International Minerals & Chemical Corporation operations in the Tennessee brown-rock phosphate fields are described in an article published early in 1942.[17]

According to the Annual Report of the Tennessee Valley Authority, studies during the fiscal year 1941 were directed toward improving several steps in the large-scale processes for manufacturing concentrated superphosphate and calcium metaphosphate. Further work was done, on a pilot-plant scale, in developing the blast-furnace process for producing phosphoric acid. Successful operation of a pilot plant was attained for the production of fused rock phosphate fertilizer of low fluorine content, and preliminary work was begun on the development of a process for producing fertilizer by fusing rock phosphate with olivine. Small-scale studies of various processes for manufacturing dicalcium phosphate fertilizer were initiated. As in previous years, the large-scale experimental fertilizer plant was employed to produce superphosphate and calcium metaphosphate. Part of the superphosphate was sold to the Agricultural Adjustment Corporation; the remainder, as well as all the calcium metaphosphate, was used in tests and farm demonstrations. Although operation of the plant was curtailed in the later months of the year to make additional power available for defense industries, production was greater than in the previous year. Several thousand tons of elemental phosphorus from the Muscle Shoals plant have gone into the manufacture of war materials. This plant is now being adapted so that almost its full capacity may be used for producing elemental phosphorus.

In Tennessee, construction work was under way during the year by T. V. A. at several localities, including a mining and washing plant in the Bear Creek area for the recovery and treatment of phosphate rock from the Authority's own deposits and a sintering unit at Godwin, near Columbia, for preparing material to be shipped to Muscle Shoals, Ala.

Virginia.—The Southern Mineral Products Corporation, subsidiary of the Vanadium Corporation of America, operated its open-cut mine on a body of apatite-bearing titanium ore (nelsonite) at Piney River and treated the mined material in its nearby mill to separate and recover apatite and ilmenite.

The occurrence and origin of the titanium-bearing deposits of Nelson and Amherst Counties have been described in detail by Ross.[18]

Sawyer and Whittemore[19] discuss the utilization of apatite from Virginia in the preparation of refractories; Whittemore,[20] in a short accompanying paper, considers the ceramic possibilities of apatite from that State. He points out that in the manufacture of a suitable aggregate or grog from Virginia kyanite for the refractories industries a "small addition of apatite was a very effective flux and mineralizer with aluminosilicates." An analysis of the fluorapatite from Piney River is given in the article.

Western States.—In 1941, Idaho, Montana, and Utah were the only Western States that produced phosphate rock. In Idaho the Anaconda Copper Mining Co. operated its No. 3 mine at Conda, Caribou County. Montana had two producers. The larger of these—the Montana Phosphate Products Co., of Trail, British Columbia—operated the Anderson and Graveley mines and Federal Government leases, shipping the mined phosphate rock to the Consolidated Mining & Smelting Co. of Canada, at Trail. The other producer—the Mineral Hill Mining Co.—operated its mine near Avon, Powell County, and shipped the crude phosphate rock to the Anaconda Copper Mining Co. at Anaconda. In Utah John M. Uren and the Garfield Chemical & Mfg. Co. mined and shipped phosphate rock from Government-leased land near Spanish Fork, Utah County.

Early in 1942, the Teton Phosphate Co., Boise, Idaho, began to ship phosphate rock from its holdings near Montpelier, Idaho.

The plant of the Anderson Phosphate Co. near Garrison, Mont., is reported to have been destroyed by fire late in 1941.

Idaho phosphate rock carries a small percentage of vanadium oxide; this material, needed for special steel alloys for war purposes, is recovered from these ores by the Anaconda Copper Mining Co. as a byproduct of its treatment of the phosphate rock from Conda.

In a recent report Richardson[21] describes the geology of a phosphate area in the Randolph quadrangle which covers northeastern Utah and southwestern Wyoming. Small amounts of phosphate rock formerly were mined in this region.

On November 12, 1941, Secretary of the Interior Harold L. Ickes announced the formation of a consulting committee which, it is reported, will investigate the possibilities of the production of low-cost fertilizer and its distribution to the farmers of the Northwest.

Western States phosphate rock sold or used by producers, 1937–41

FOREIGN TRADE[22]

Imports.—Total imports of phosphate rock declined gradually from 13,400 long tons in 1937 to 2,953 tons in 1940. Because of war restrictions, data on imports in 1941 are available for publication for the first 9 months only; during this period neither phosphate rock nor apatite was imported. Imports of ammonium phosphates used as fertilizer declined sharply in 1941, only 4,858 long tons entering the

Precipitated bone, fertilizer grade	4,414	120,225	3,385	98,725	2,314	68,611	1,141	38,225		

Exports.—Because of wartime restrictions on release of foreign trade data for 1941, the total quantity and value of exports from January to September only can be published; exports by countries of destination cannot be published. Exports of phosphate rock were much larger in these 9 months than in the whole 12 months of 1940. Florida land pebble and hard rock, and Western States hard rock also, were exported; as in former years, the greater part of the exports was Florida land pebble.

The accompanying tables show shipments of phosphate rock and "Other phosphate materials" from the United States in the years 1937 to 1940, inclusive, and in the first 9 months of 1941.

Phosphate rock [1] exported from the United States, 1937–41

Year	Long tons	Value: Total	Value: Average	Year	Long tons	Value: Total	Value: Average
1937	1,052,802	$5,818,231	$5.53	1940	751,495	$3,845,495	$5.12
1938	1,140,841	6,637,638	5.82	1941 (Jan.-Sept.)	820,396	4,600,449	5.61
1939	949,006	5,233,104	5.51				

[1] 1937–40: Excludes sintered matrix, which is included under "Other phosphate materials"; 1941: Includes sintered matrix.

Other phosphate materials [1] exported from the United States, 1937–41

Year	Long tons	Value	Year	Long tons	Value
1937	55,665	$466,850	1940	11,924	$201,047
1938	32,581	208,550	1941 (Jan.-Sept.)	1,870	94,780
1939	29,080	192,306			

[1] 1937–40: Includes bone ash, dust, and meal; animal carbon for fertilizer; basic slag, etc.; and sintered matrix. 1941: Excludes sintered matrix, which is included under "Phosphate rock."

WORLD RESERVES

The total phosphate-rock reserves of the world are now believed to exceed 26 billion tons [23]—nearly 13¾ billion tons in North America (13½ billion in the United States alone), nearly 8 billion tons in Europe (roughly 7½ billion tons in Russia), and over 3½ billion tons in Africa (by far the greater part in French North Africa). The remaining reserves, less than a billion tons, are scattered over South America Oceania, and Asia. These data are shown graphically in the following diagram (fig. 4).

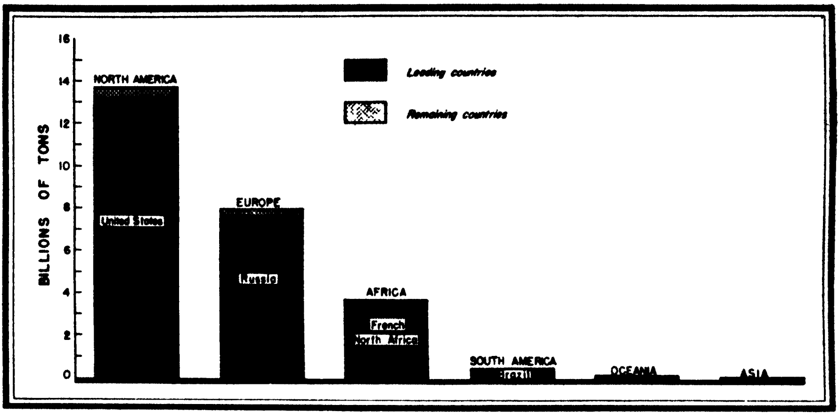

FIGURE 4.—Known phosphate-rock reserves of the world, by continents and countries, in 1942.

WORLD PRODUCTION

Few figures are available on phosphate production in foreign countries during 1941 (see following table). Presumably little change occurred in the general trends, save in the Mediterranean region and in Oceania.

In Canada, activity revived on a small scale at certain long-idle apatite mines of the Liévre River district, Quebec.[24]

TECHNOLOGIC DEVELOPMENTS

Several papers on various phases of phosphate-rock technology, in addition to those mentioned in other parts of this chapter, have appeared; they are referred to briefly here.

Easterwood [25] discusses several of the more recent developments in the phosphate industry.

Copson, Pole, and Baskervill [26] describe methods of producing metaphosphates of calcium, potassium, and sodium.

[1] In addition to countries listed, Austria, Belgium, Poland, and Taiwan produce phosphate rock, but data of output are not available.
[2] Estimated
[3] Data not available.
[4] Estimated (Imp. Inst., London).
[5] Including exports as follows: 1937, 1,484,562 tons; 1938, 1,427,643 tons; 1939, 1,465,673 tons.
[6] Exports during fiscal year ended June 30 of year stated.

Schwartz and Munter[27] discuss in considerable detail the uses of various sodium and potassium phosphates in water softening.

Elmore, Huffman, and Wolf[28] present the results of a study of the defluorination of phosphate rock.

Larpenteur[29] discusses the application of hydroseparation and classification in the treatment of washer debris in the Florida land-pebble and Tennessee brown-rock phosphate fields.

Walthall and Striplin[30] describe the pilot-plant development of a process for manufacturing phosphoric acid by burning phosphorus in dry air and absorbing the resulting P_2O_5 vapor in concentrated aqueous solutions containing 85 percent P_2O_5.

Earhart [31] presents a study of the economic advantages and ceramic possibilities of using phosphates as opacifying agents in glazes.

Crass [32] describes the use of phosphorus in the match industry.

The use of phosphates in ceramic ware is described in a series of papers by Weyl,[33] Weyl and Kreidl,[34] and Kreidl and Weyl.[35]

Brunauer and Shultz [36] show that if phosphate rock is present when phosphorus is oxidized by steam at 1,000°–1,100° C. certain undesirable products—phosphorus tetroxide and phosphine—are eliminated.

Armstrong [37] discusses phosphate treatment as a rust preventive before painting.

The uses of various phosphates in ceramics are discussed in a recently issued Dictionary of Ceramic Materials.[38]

SUPERPHOSPHATES

The following table gives outstanding features of the superphosphate industry in the United States from 1938 to 1941.

Salient statistics of the superphosphate industry in the United States, 1938–41

	1938	1939	1940	1941
Production: [1]				
Bulk superphosphate ....short tons..	3,575,588	3,801,194	4,385,971	4,867,202
Wet base and wet mixed goods........do....	156,730	152,500	136,204	136,631
Shipments: [1]

Superphosphates (acid phosphates) imported for consumption in the United States, 1939–41, by classes and countries

Class and country	1939		1940		1941 (Jan.–Sept.)	
	Long tons	Value	Long tons	Value	Long tons	Value
Normal (standard) (not over 25 percent P_2O_5 content):						
Belgium	450	$6,717				
Canada	9,864	145,772	7,057	$97,682	4,174	$56,187
Germany	198	2,124				
Netherlands	1,635	14,769				
	12,147	169,382	7,057	97,682	4,174	56,187
Concentrated (treble) (over 25 percent P_2O_5 content):						
Belgium	4,142	134,208				
Canada	552	23,140	2,864	39,982	2,788	69,356
Netherlands	250	7,955				
	4,944	165,303	2,864	39,982	2,788	69,356
Ammoniated:						
Belgium	27	1,585				
Canada	120	3,607	96	1,951	18	376
	147	5,192	96	1,951	18	376
	17,238	339,877	10,017	139,615	6,980	125,919

Exports of superphosphates in recent years are shown in the following table; both the total quantity and value increased yearly from 1937 to 1940, but figures for the first 9 months of 1941 appear to indicate at least temporary cessation of growth in quantity (but not value) and virtual doubling of the average value per ton.

Superphosphates exported from the United States, 1937–41

Year	Long tons	Value: Total	Value: Average	Year	Long tons	Value: Total	Value: Average
1937	78,949	$841,062	$10.65	1940	141,289	$1,655,336	$11.72
1938	90,237	945,351	10.48	1941 (Jan.–Sept.)	102,784	2,203,836	21.44
1939	95,224	1,010,336	10.61				

Supplies of phosphate rock ample for the manufacture of superphosphates needed by this country are available at the mines. However, inadequate facilities for transporting this necessary raw material to the superphosphate-producing centers, increased demands by the munitions industry for sulfuric acid—the other essential in the manufacture of superphosphates—and consequent possible shortage of supply for fertilizer manufacture, and increased demands for superphosphate affected prices, which were advanced slightly late in 1941. On February 21, 1942, a price ceiling established on superphosphate fixed the price [39] at that prevailing within 5 days before the temporary regulation was issued.

[39] Office of Price Administration, Title 32.—National Defense: Chap. 11, part 1367—Fertilizers—Temporary Maximum Price Regulation No. 1. Mixed Fertilizers, Superphosphate, and Potash.

Temporary price maximums for superphosphate, which expired April 27, 1942, were made permanent under Maximum Price Regulation 135, effective April 28, 1942, stabilizing the prices at the levels prevailing since February.

Several articles relating to the technology of the superphosphate industry appeared recently.[40]

BASIC SLAG

Basic slag is an important source of fertilizer phosphorus in many European countries, where it has become an active competitor of phosphate rock and superphosphate for that purpose in agriculture. No figures for production in Europe during 1939, 1940, or 1941 are available; data for 1935–38 are given in Minerals Yearbook, 1940, Review of 1939, p. 1319. A total of at least 4 to nearly 6 million tons is produced annually.

Little basic slag is produced in the United States—probably 25,000 to 50,000 tons a year in the Birmingham iron district of Alabama.

Only a small quantity of basic slag is imported into the United States annually. Such imports in recent years (1937–40) ranged from 405 to 714 long tons. Annual figures, 1937–41, are given in the section of this chapter on "Foreign trade."

TALC, PYROPHYLLITE, AND GROUND SOAPSTONE [1]

By Bertrand L. Johnson and K. G. Warner

SUMMARY OUTLINE

GENERAL CONDITIONS

Sales of talc, pyrophyllite, and ground soapstone in 1941 were 416,369 short tons valued at $4,701,892 (see fig. 1), or 48 percent (134,994 tons) greater in quantity and 56 percent ($1,693,572) greater in value than in 1940. Sales of crude, sawed and manufactured, and ground all increased in both quantity and value—the greatest tonnage

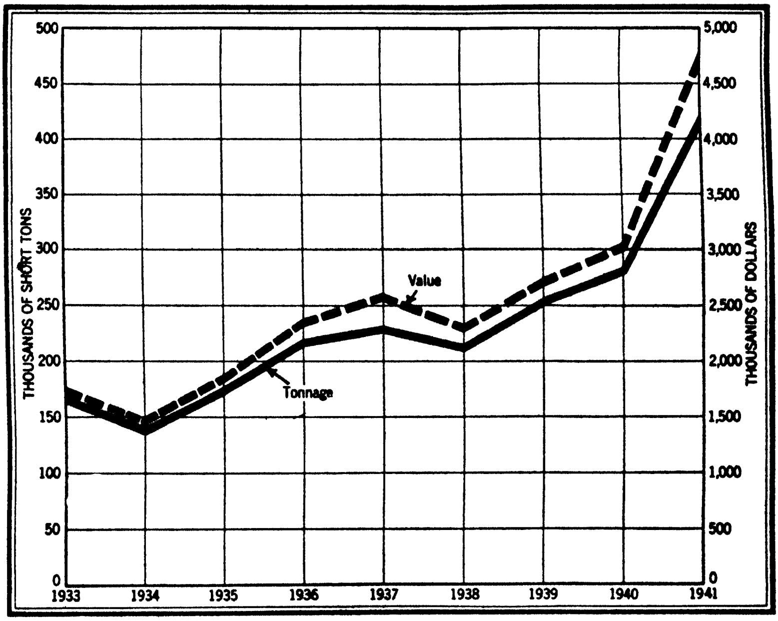

Figure 1.—Sales of domestic talc, pyrophyllite, and ground soapstone, 1933–41.

increase being in the ground products. Imports of crude materials were greater in both quantity and value in the 9 months of 1941 for which figures may be published than in the entire year 1940, but imports of other classes were less in both categories. Exports (both classes) for which data are available were less in the first 9 months of 1941 than in the whole year 1940.

[1] Soapstone sold in slabs or blocks is included in the chapter on Stone.

Pyrophyllite is included with talc in this discussion because it resembles talc in certain physical properties and is interchangeable with talc in some uses, although during recent years certain specialized uses for pyrophyllite have been developed. It is a hydrous aluminum silicate, $Al_2Si_4O_{10}(OH)_2$, whereas talc is a hydrous magnesium silicate, $Mg_3Si_4O_{10}(OH)_2$. Pyrophyllite sometimes is classed as one of the kaolin minerals (see Minerals Yearbook, 1939, p. 1273).

Salient statistics of the talc, pyrophyllite, and ground soapstone industries in the United States, 1940–41

	1940		1941	
	Short tons	Value	Short tons	Value
Mined:

		1,113,522		[4] 1,011,775

[1] Data not available.
[2] Includes pinite from Nevada.
[3] Exclusive of "manufactures, n. s. p. f., except toilet preparations," as follows: 1940, $21,568; 1941 (January–September), $9,915, quantities not available.
[4] Figures cover January to September, inclusive.
[5] Quantity not recorded.

Eleven States reported sales of talc, pyrophyllite, ground soapstone, or pinite in 1941, the same number as in 1940, but Montana replaced New Jersey as a producer. Western States increased their share of the total domestic sales from 14 to 17 percent. Eastern States furnished the remaining 83 percent in 1941—a slight decline from 1940 in relative performance.

SALES

Sales of talc, pyrophyllite, and ground soapstone by producers increased greatly in 1941 and reached an all-time record of 416,369 short tons valued at $4,701,892 (see fig. 1), an increase of 48 percent in quantity and 56 percent in value over 1940. Sales of crude, sawed and manufactured, and ground materials were all greater than in 1940. The increase in sales of crude material, however, was not as great as it appears, for this year the Bureau has attempted to record the crude sold by the primary producers.

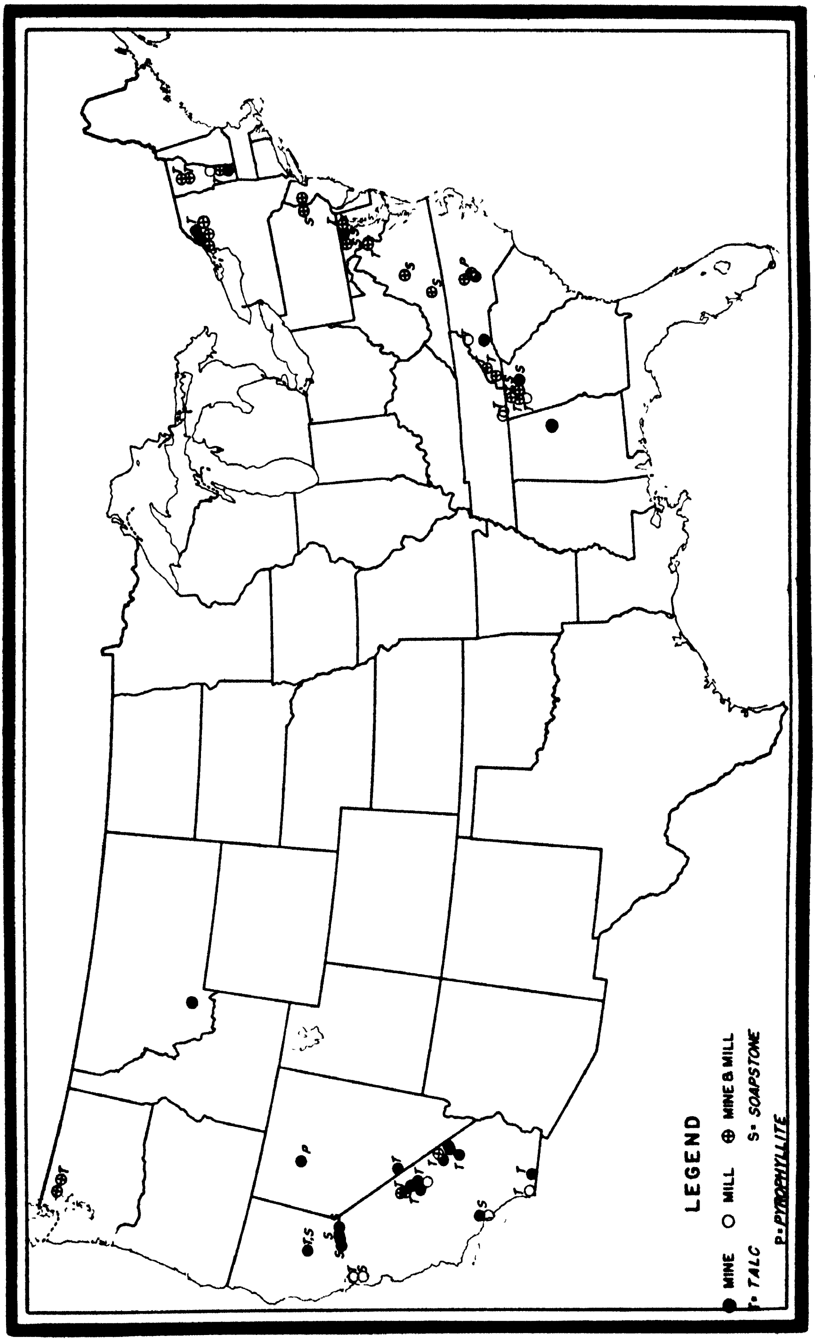

FIGURE 2.—Location of talc, pyrophyllite, and soapstone mines and mills in the United States.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1937–41, by classes

Year	Crude			Sawed and manufactured

1940	261,757	2,749,331	10.50	281,375	3,008,320	10.69
1941	368,360	3,999,586	10.86	416,369	4,701,892	11.29

[1] Includes pinite from Nevada.

Sales by States.—Markedly larger tonnages were sold or used by producers in 1941 in all States for which comparative figures can be published for 1940 and 1941, and increases ranged from 35 to 65 percent. The greatest advances in tonnage sold were in New York, North Carolina, California, and Vermont. All-time high records are known to have been established in California, Georgia, North Carolina, and New York. New York remained by far the leading producing State; its output was more than double that of any other State.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1940–41, by States

State	1940		1941	
	Short tons	Value	Short tons	Value
California	36,282	$476,926	59,203	$811,793
Georgia	20,104	219,959	28,511	364,560
Maryland	(1)	(1)	15,628	105,363
Nevada	(1)	(1)	[2] 13,178	[2] 126,433
New York	113,611	1,402,524	153,560	1,917,732

[2] Includes Nevada pinite.
[3] 1940: Maryland, Nevada, New Jersey, Pennsylvania, and Virginia; 1941. Montana, Pennsylvania, and Virginia.

MARKETS

The paint, ceramics, rubber, roofing, and paper industries consume most of the talc, pyrophyllite, and ground soapstone of domestic origin. Reports from producers to the Bureau of Mines show that these five industries took 81 percent of the total sales in 1941 compared with 75 percent in 1940. The tonnage of these commodities used by all the principal consuming industries increased sharply, an advance of over 52,000 tons being reported for the paint industry alone. The ceramic industry retained its position as the second most important market and again slightly increased its share of the total. The rubber industry more than doubled its consumption and rose to third place. Consumption in toilet preparations made a notable rise—about 140 percent—probably indicative of the replacement of foreign talcs by those of domestic origin.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1940–41, by uses

Use	1940		1941	
	Short tons	Percent of total	Short tons	Percent of total
Paint	67,875	24	120,319	29
Ceramics	48,661	18	78,990	19
Rubber	28,501	10	58,114	14

Use not reported	24,653	9	14,688	3
	[3] 281,375	100	[3] 416,369	100

[1] Included under "Other uses"; figures not available.
[2] 1940 Bleaching, insecticides, plaster, refractory, textile, and other minor uses, 1941. Bleaching, insulation, lubricants, refractory, textile, and other minor uses.
[3] Includes pinite.

PRICES

The average values of sales of all grades of talc, pyrophyllite, and ground soapstone in the past 5 years, as reported to the Bureau of Mines by producers, are given in the table under Sales.

Quotations on finely ground domestic talc, per ton, f. o. b. works, carlots, on May 18, 1942, were as follows, according to the Oil, Paint and Drug Reporter:

California: $17.50 to $43.

New York: Fibrous, 325-mesh, 93 to 94 percent, $13 to $18; 99 to 99½ percent, $15.25 to $19.25; 99.95 percent, $17 to $21.

Pennsylvania: $11 to $13.50.

Vermont: $14.

Canadian talc: Carlots, delivered New York, quoted at $24 to $30 a ton.

No quotations were available on imported French and Italian talcs.

The quoted prices on pyrophyllite in the same journal were: Standard, 200-mesh, carlots, mines, $10 a ton; 325-mesh, $13; No. 3, 200-mesh, carlots, mines, $8 a ton; 325-mesh, $11. All represent

increases over quotations of a year earlier, except the last one which declined from the previously published figure of $12 a ton.

DEVELOPMENTS IN THE INDUSTRY

Talc.—Stimulated by the war need for high-frequency radio-electric insulating materials, the demand for steatite products has greatly increased. Several articles have appeared relating to the preparation and uses of such products.

Gunzenhauser[2] has presented two recent papers. The first discusses in considerable detail the use of steatitic talc and soapstone and the various methods of treating the raw materials in the preparation of the numerous types of ceramic products for insulation; the second discusses the conversion of a whitewares plant to the production of steatite.

An electric kiln developed by the Tennessee Valley Authority in the course of ceramics research at Norris, Tenn., was made available late in 1941 to the American Lava Corporation, of Chattanooga. The purpose was to avert a bottleneck in the production of steatite electric insulators for radios pending installation of increased kiln facilities at the Chattanooga plant. Since August 1940 the kiln has been operated by the Bureau of Mines under lease from the Authority, in continuation of a research program on the use of electricity in the nonmetallic mineral industries. The unfired insulators are transported from Chattanooga to Norris by truck, and finished ware is taken back. Labor for the kiln is provided by the American Lava Corporation.[3]

Thurnauer and Rodriguez[4] surveyed the literature on the crystal structure of calcined talc and steatite materials and presented the results of a study of the changes in the structure of talc and steatite bodies brought about by varying heat treatment and by the addition of different fluxes.

O'Meara,[5] of the Bureau of Mines, reported the results of a survey of domestic talcs that were obtained from various producers and from different deposits.

A new use for ground talc is in the smothering of incendiary bombs, and Canadian talc is now being shipped to Great Britain for this purpose.[6]

Davies, Pask, and Zwermann[7] presented the results of a study of talc samples. Dried and fired properties and the relation between acid solubility and physical properties were determined in four series of bodies.

Pyrophyllite.—In 1937 Greaves-Walker and associates[8] presented the results of a study of the use of pyrophyllite in refractories, which indicated that this mineral could be made into a very satisfactory fired product with properties equal or superior to those of high-heat-duty refractories. In 1941 Greaves-Walker and Amero[9] reported upon the use of pyrophyllite in unfired refractories; they concluded that a satisfactory unfired dry-pressed refractory for high heat duty may be produced, employing pyrophyllite as the major ingredient, with various specified bonding agents. The refractory would be used in operations not requiring it to come in contact with highly ferruginous or strongly basic slags.

Blume[10] describes a method of testing the fusion characteristics of nonplastic materials containing pyrophyllite, in which feldspar and flint are varied and pyrophyllite is constant.

According to Ceramic Industry,[11] pyrophyllite is used in the ceramic industry in wall-tile bodies, semivitreous dinnerware, electrical insulator bodies, and enamels. In wall-tile bodies, substitution of pyrophyllite for part or all of the flint or feldspar causes a decrease in thermal expansion, with resultant decrease in tendency of both body and glaze to fail when subjected to sudden temperature changes. Pyrophyllite in wall-tile bodies is said to increase the firing range but to decrease crazing due to thermal shock or moisture expansion, fire-cracking, and shrinkage with a resultant decrease in warpage, and to reduce wear on molds and dies.

According to the same authority, pyrophyllite is being used with talc to a limited extent in the manufacture of semivitreous dinnerware, but both minerals show a marked tendency to decrease the workability of a plastic body; for this reason, quantities sufficient to obtain the best results are not used. The total amount of pyrophyllite and talc in a dinnerware body should not exceed 20 percent; if this maximum amount is used the body should be deaired, otherwise it will work too short. When properly used, pyrophyllite will decrease the thermal and moisture expansion of semivitreous dinnerware bodies with a resulting decrease in the tendency to craze. In electrical insulation bodies very large amounts have been successfully used; it is said that bodies containing 94 to 96 percent pyrophyllite compare favorably with porcelain in mechanical and electrical characteristics and may be employed in applications not requiring high puncture values or zero porosity. They were stated to be superior to porcelain but inferior to steatite for certain high-frequency applications. Pyrophyllite is being increasingly used as a source of alumina for enamels.

Some service records of pinite, a hydrothermally altered acidic tuff suitable as a refractory lining, are summarized in a recent article.[12] This rock, composed of a mixture of sericite and pyrophyllite, is mined near Rochester, Nev. (see Minerals Yearbook, Review of 1940, p. 1291).

FOREIGN TRADE [13]

Imports.—In the first 9 months of 1941, imports for consumption of "talc, steatite or soapstone, and French chalk" were 14,908 short tons valued at $194,511; figures for the entire year cannot be published.

In 1941, as in recent years, nearly all the imports consisted of materials "ground, washed, powdered, or pulverized, except toilet preparations"; only about 2 percent was of "crude and unground" and "cut and sawed" materials.

The "crude and unground" material imported during the first 9 months of 1941 totaled 223 short tons—130 tons from British India and all but 2 tons of the remainder from China and the Union of South Africa. The "cut and sawed" varieties imported in the January-September period of 1941 came entirely from Japan. Imports in the "ground, washed, powdered, or pulverized" category in the first 9 months of 1941 from both France and Italy dwindled to only a few tons each; imports from Japan proper were slightly greater in the first 9 months of 1941 than in the entire year 1940, but imports from Kwantung (Japanese-leased territory) appear separately as 3,669 tons in the first 9 months of 1941, whereas they are not itemized in the 1940 record; and imports from British India were 1,065 tons in the first 9 months of 1941, with a value of $12,705. However, declared exports of ground talc from the port of Karachi in India to the United States in the first 6 months of 1941 are said to have been valued at $76,991 compared with $25,835 in the same months of 1940.[14] Canada was the principal source of this grade of talc, and imports from that country during the first 9 months of 1941 were slightly greater than in the entire year 1940.

WORLD PRODUCTION

Few production figures for talc, pyrophyllite, and soapstone by countries in 1941 are available. The only figures for the entire year 1941 are those for the United States and Uruguay. Production for the first 6 months of 1941 is given for the Union of South Africa.

Data available indicate that the United States is still by far the leading producing nation and is steadily increasing that lead.

In Scotland an impure grade of talc is being produced in Banffshire so that former imports from France and Italy can be partly replaced.[15] The talc deposits associated with the British serpentines were described in a publication issued in 1941.[16] The Indian talc deposits were described by Lees.[17] In Newfoundland some pyrophyllite is said to have been mined and shipped to England. In Canada, according to a letter in December 1941 from W. B. Timm, Director, Mines and Geology Branch, Canadian Department of Mines and Resources, to Oliver Bowles, of the Bureau of Mines, the talc industry is reported to have been extremely active throughout the year, with established producers working at capacity. As in recent years, the production came from the Madoc district, Ontario, and the Eastern Townships, Quebec. Two small new operators started work in the Madoc field in the latter part of 1941. Canadian talc is also [18] being ground for toilet preparations because Italian talc is no longer available.

World production of talc and soapstone, 1937–41, by countries, in metric tons [1]

FLUORSPAR AND CRYOLITE

By H. W. DAVIS [1]

SUMMARY OUTLINE

FLUORSPAR

The domestic fluorspar industry was called upon to supply an unprecedented demand in 1941 in order to meet the requirements of steel mills and aluminum plants (both of which made new production records) and to supply the greatly accelerated needs of manufacturers of glass, enamel, and hydrofluoric acid. Producers responded by shipping 320,669 short tons of fluorspar and thus established a new record. Shipments were 37 percent greater than in 1940 and 22 percent more than the previous record (263,817 tons) made in 1918 during World War I. Shipments in 1941 were adequate not only to cover consumption, but they enabled consumers to increase inventories slightly. Moreover, there was only a small decline in stocks at mines. Shipments from Kentucky, Nevada, New Mexico, and Utah established all-time highs; the movement from Illinois (133,333 tons), although second-largest on record, was 15 percent less than the peak of 156,676 tons in 1917. Shipments by river or river-rail (74,616 tons) also made a new record. Sales of imported fluorspar, however, were 31 percent less than in 1940. On the other hand, shipments for foreign consumption, which usually are small, jumped to 12,184 tons and for the first time exceeded imports.

Sales of fluorspar to consumers in the United States totaled 316,074 short tons in 1941 (308,485 tons from domestic mines and 7,589 tons from foreign sources) compared with 236,042 tons in 1940 (225,118 tons from domestic mines and 10,924 tons from foreign sources). Total sales to the domestic steel industry increased to 220,222 tons in 1941 from 172,047 tons in 1940, sales to manufacturers of hydrofluoric acid (essential in the manufacture of artificial cryolite and aluminum fluoride—aluminum raw materials) advanced to 54,092 from 35,242 tons, and sales to makers of glass and enamel jumped to 32,051 from 20,280 tons.

[1] Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce; those on shipments of fluorspar for foreign consumption supplied by the producers. No exports recorded by the Department of Commerce.

Despite the unprecedented demand for fluorspar in 1941, the average composite selling price ($20.98 a ton) of all grades (both domestic and foreign) delivered to consumers in the United States was only slightly more than in 1940 ($20.40). The average selling price f. o. b. Illinois-Kentucky mines of fluorspar shipped to domestic steel plants was $19.62 a short ton ($18.93 in 1940), of that shipped to manufacturers of hydrofluoric acid $26.78 ($26.10 in 1940), and of that to makers of glass and enamel $27.39 ($28.26 in 1940). The average selling price at seaboard (duty paid) of imported fluorspar shipped to steel plants was $23.58 a short ton in 1941 ($22.03 in 1940) and of that shipped to makers of hydrofluoric acid $27.33 ($27.44 in 1940).

The Office of Price Administration on January 20, 1942, requested producers not to publish or quote prices on or sell fluorspar at prices above those in effect on January 2, 1942.

Fluorspar was placed on the list requiring license for export by official order published May 13, 1941.

Salient statistics of the fluorspar industry in the United States, 1940–41

[1] Figures not available. [2] Revised figures. [3] January to September, inclusive.

The total quantity of fluorspar shipped in and imported into the United States from about 1870 through 1941 was approximately 5,907,000 short tons, comprising about 82 percent from domestic mines and 18 percent from foreign sources.

The total shipments since commercial production was begun (around 1870) in the United States through 1941 were approximately 4,848,000 short tons, of which Illinois and Kentucky contributed 56 and 36 percent, respectively. Imports of fluorspar into the United

States from 1910 through 1941 were about 902,000 short tons, and imports before 1910 are estimated at 157,000 tons—a total of about 1,059,000 tons, of which the United Kingdom and Germany contributed 50 and 20 percent, respectively.

Fluorspar shipped[1] from mines in the United States, 1880–1941, by States, in short tons[2]

PRODUCTION AND SHIPMENTS

Production of fluorspar (expressed in terms of finished product) totaled 313,000 short tons in 1941 compared with 244,000 tons in 1940. Of the output in 1941, 7 mines producing over 10,000 tons each supplied 106,000 tons or 34 percent, 14 mines producing 5,000 to 10,000 tons each supplied 102,000 tons or 33 percent, 26 mines producing 1,000 to 5,000 tons each supplied 63,000 tons or 20 percent,

and 12 mines producing 500 to 1,000 tons each supplied 8,000 tons or 2 percent. Thus, 59 mines produced 279,000 tons or 89 percent of the total. The remainder (34,000 tons or 11 percent) was produced in quantities ranging from a few tons to 500 tons from an undetermined number of small mines and prospects and reclaimed from mill ponds, waste dumps, and old workings of abandoned mines.

Fluorspar shipments from domestic mines in 1941 were the largest on record; they aggregated 320,669 short tons valued at $6,724,782, increases of 37 percent in quantity and 42 percent in total value over 1940, and were equivalent to 257 percent of the average annual tonnage shipped in the 5-year period 1926–30. Of the 1941 total, 74,616 tons (an all-time high) was shipped by river or river-rail for delivery to consumers in Illinois, Indiana, Kentucky, Ohio, Pennsylvania, and West Virginia.

In 1941, mines operated by or for consumers shipped 59,644 short tons of fluorspar for use in their own plants compared with 53,162 tons in 1940.

The average value of all grades of domestic fluorspar shipped in 1941 was $20.97 a short ton ($0.66 more than the 1940 average).

The following table shows shipments of fluorspar, by States, during 1940 and 1941.

Fluorspar shipped from mines in the United States, 1940–41, by States

State	1940			1941		
	Short tons	Value		Short tons	Value	
		Total	Average		Total	Average

SHIPMENTS, BY USES

The steel industry is the predominant purchaser of fluorspar, as is evident from the following table; it also consumes considerable hydrofluoric acid and sodium fluoride, in which fluorspar is the basic material.

Fluorspar shipped from mines in the United States, 1940–41, by uses

Use	1940				1941			
	Quantity		Value		Quantity		Value

USES

As figure 1 shows graphically, the steel industry is the chief consumer of fluorspar in the United States. The second-largest use is in the manufacture of hydrofluoric acid, which is employed to make artificial cryolite and aluminum fluoride (aluminum raw materials) and refrigerating mediums; hydrofluoric acid is also used in the electrolytic refining of metals, the pickling of metals, chromium plating, and the etching of glassware, as well as for other purposes. The glass and enamel industries rank third and fourth, respectively, in importance. Comparatively small quantities of fluorspar are used in a number of miscellaneous operations, such as production of the finer grades of iron castings, chilled-iron rolls, brass and bronze ingots, nickel and Monel metal, magnesium, cement, ferro-alloys, carbon electrodes, and calcium carbide and cyanamid; in refining lead and silver; in extracting various rare metals from their ores; in smelting refractory ores of gold,

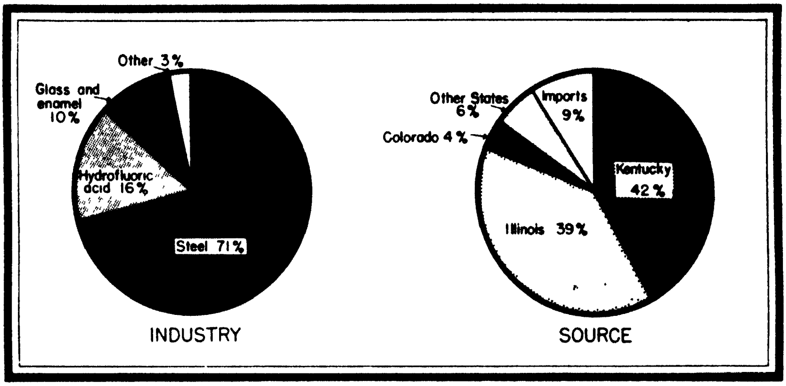

FIGURE 1.—Average annual fluorspar sales (domestic and foreign) to consumers in the United States, 1937–41, by consuming industries and by sources.

silver, and copper; as a paint pigment; as a binder for abrasives; and in a formula for coating welding rods.

Consumption of fluorspar in the manufacture of bessemer steel was reported to the Bureau of Mines for the first time in 1941. According to The Foundry: [2]

> While it is well-known that the basic bessemer process reduces the phosphorus content of steel, it is only recently that dephosphorization has been applied to the acid bessemer process using cold fluxes. Flux employed is composed of 50 percent impure lime, 30 percent dry roll scale, and 20 percent fluorspar. In use the regular slag formed after blowing the heat is removed by holding it back with a wooden block as the molten steel is poured into the ladle. The cold flux is added to the stream flowing into the ladle at a rate to insure a good boiling action. Reaction is said to be complete in about 30 seconds, and the phosphorus reduced from 0.095 to 0.100 percent to 0.020 to 0.040 percent in that time.

A comparatively small quantity of sodium fluoride—a derivative of hydrofluoric acid—is used in the steel industry. According to Metals and Alloys: [3]

> Rimming steels generally contain 0.12 percent C maximum and 0.5 percent Mn maximum. Solidification is decidedly affected by the evolution of gas, mainly carbon monoxide, resulting either from reaction or reduced solubility. The

[2] The Foundry, May 1941, vol. 69, No. 5, p. 146.
[3] Metals and Alloys, April 1941, vol. 13, No. 4, p. 472.

principal recent innovations in manufacture are (1) special molds (their use is widespread in America) and (2) use of sodium fluoride. Sodium fluoride additions have an effect opposite to that of aluminum, namely, they speed up the effervescence of the ingot. The standard procedure is to add 2 ounces per ton during teeming. The effect is most marked in small ingots in which the height to cross-section ratio is over 4 : 1. Sodium fluoride addition at the start of pouring increases the rimming action in the lower half of the ingot, thereby giving an ingot with more uniform skin thickness and surface quality. Sodium fluoride is especially useful for heats that are somewhat sluggish in rimming and that might give second-grade ingots.

Chief commercial grades of fluorspar

Name	Chief use	Form	Specifications, in percent		
			CaF_2 (minimum)	SiO_2 (maximum)	Fe_2O_3 (maximum)
Metallurgical	Basic open-hearth steel.	Washed gravel, less than 1 inch and not more than 15 percent of fines.	85	5	
Ceramic	Glass and enamel	Ground: Coarse, fine, and extra fine.	95	3	0.12
Acid	Hydrofluoric acid	Lump, gravel, and ground	98	1	

CONSUMPTION AND CONSUMERS' STOCKS

The following tables give data on consumption and consumers' stocks of fluorspar.

Fluorspar (domestic and foreign) consumed and in stock in the United States, 1940–41, by industries, in short tons

Industry	1940		1941	
	Consumption	Stocks at consumers' plants Dec. 31	Consumption	Stocks at consumers' plants Dec. 31
Basic open-hearth steel	143,800	79,800	191,300	84,200
Electric-furnace steel	11,700	1,700	18,300	2,500
Foundry	2,700	900	2,600	1,000
Ferro-alloys	1,900	900	2,500	1,000

Consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1937–41

	1937	1938	1939	1940	1941
Production of basic open-hearth steel ingots and castings ... long tons	46,361,000	25,868,000	43,368,000	55,038,000	65,993,000
Consumption of fluorspar in basic open-hearth steel production ... short tons	138,900	73,600	116,200	143,800	191,300
Consumption of fluorspar per ton of steel made ... pounds	6.0	5.7	5.4	5.2	5.8
Stocks of fluorspar on hand at steel plants at end of year ... short tons	71,400	55,000	69,900	79,800	84,200

The quantity of fluorspar used by individual plants per long ton of basic open-hearth steel produced ranges from 1 to 50 pounds—a relatively small proportion of the furnace charge. The average is generally 5 to 8 pounds. It is noteworthy that from 1921 (the first year for which these data were collected) to 1940 the average consumption of fluorspar per ton of steel made declined almost steadily from 8.2 to 5.2 pounds. However, it increased to 5.8 pounds in 1941. The gain in 1941 was due partly to the manufacture of proportionately more armor steel, a poorer quality of scrap, higher charges of lime, and rushing of heats. Although electric-furnace steel plants are small users of fluorspar as compared with basic open-hearth steel plants, the average consumption of fluorspar (14 pounds) per long ton of electric steel made is substantially greater. The following table shows the variation in average consumption of fluorspar per ton of basic open-hearth steel over a 5-year period in certain plants that make about 88 percent of the total.

Average consumption of fluorspar (domestic and foreign) per long ton of steel, 1937–41, in pounds

1937	1938	1939	1940	1941	1937	1938	1939	1940	1941

QUOTED PRICES

According to Iron Age, in 1941 the quoted price f. o. b. Illinois-Kentucky mines for fluxing gravel and No. 2 lump fluorspar increased from \$20 a short ton on January 1 to \$25 by December 31. Smaller increases were made in the quoted prices of No. 1 ground and acid-grade fluorspar. Imported fluxing-gravel fluorspar (at seaboard, duty paid) was quoted nominally at \$25.50 a short ton throughout the year.

As a consequence of the price rise in fluorspar, the Office of Price Administration on January 20, 1942, notified producers of fluorspar that it regarded any further increase in prices as inimical to the national welfare and requested producers "not to publish or quote prices on, nor sell your fluorspar at prices above your prices in effect on January 2, 1942." If any fluorspar producer considers it necessary to increase prices above the January 2 level, the Administrator requested him to notify the Office of Price Administration 1 month in advance of the date upon which the intended increase would take effect and to submit a detailed factual statement of reasons that the producer believed would justify the proposed increase, including financial data.

STOCKS AT MINES OR SHIPPING POINTS

According to reports of producers, the quantity of fluorspar in stock at mines or shipping points at the close of 1941 totaled 72,197 tons, or 3 percent less than in 1940. These stocks comprised about 40,000

tons of crude fluorspar (calculated to be equivalent to 25,000 tons of finished fluorspar) and 31,997 tons of finished fluorspar.

Stocks of fluorspar at mines or shipping points in the United States, December 31, 1940 and 1941, by States, in short tons

State	1940			1941		
	Crude [1]	Finished	Total	Crude [1]	Finished	Total

[1] The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed

TECHNOLOGIC DEVELOPMENTS

The capacity of flotation plants in the United States was increased substantially in 1941 by additions to or improvements in present mills; new plants are now under construction. At the plant of the Rosiclare Lead & Fluorspar Mining Co., more flotation cells were added, the ball mill was enlarged, and other improvements were made. The Mahoning Mining Co. and Aluminum Ore Co. expanded and improved their flotation mills during 1941. The Colorado Fluorspar Corporation made improvements in its mill at Salida, Colo.; P. L. Grattan is rebuilding his flotation plant at Deming, N. Mex.; and J. Irving Crowell, Jr., installed flotation cells in his mill near Beatty, Nev. The General Chemical Co., which operates a flotation plant at Deming, N. Mex., is constructing a flotation plant near Jamestown, Colo., to treat ore from its mines in Boulder County. The Fluorspar Processing Co. is installing a combination flotation-concentrating mill near Salida, Colo. Output of flotation concentrates was 64,627 short tons in 1941 compared with 41,467 tons in 1940.

A Bendelari jig, the first to be used in the Illinois-Kentucky district, was installed in the mill of the Fluorspar Products Corporation near Rosiclare, Ill. This type of jig is also used by Navajo Fluorspar Mines in its mill near Grants, N. Mex.

Air tables, an innovation in milling fluorspar, were included in the equipment installed in the mill of the Big Creek Fluorspar Co. near Rosiclare, Ill.

A method of concentrating fluorspar ores is covered by United States Patent 2,263,552 granted to C. O. Anderson and others, assignors to Mahoning Mining Co. A principal object of the invention is to provide a method for flotation concentration of fluorspar from ores high in calcite, by means of which acid-grade fluorspar can be produced commercially without desliming treatment before flotation of the ore. A further object of the invention is to provide a method of this character that will avoid loss of material ore values through removal of the fines or slimes preparatory to flotation. Another object is to provide a method of flotation concentration of fluorspar

from ores high in calcite, in which the "middlings" can recirculate in the flow sheet without material objectionable effects.

FLUORSPAR INDUSTRY IN 1941, BY STATES

Arizona.—Production in Arizona came from mines and prospects in Greenlee and Pima Counties, and most of it was shipped to the flotation plants at Deming and Lordsburg, N. Mex. The flotation concentrates recovered from the fluorspar, instead of the run-of-mine material, have been credited to Arizona in the statistics. The flotation plant of the Southwestern Mineral Co. at Fox, Ariz., stopped milling fluorspar on April 1, 1940, and the mill was used to beneficiate complex ores from New Mexico. The fluorspar milled at the Fox plant in 1941 came from the Great Eagle and Mohawk mines in New Mexico. Plans for resuming production of fluorspar at the Fox plant in 1942 are under consideration. Bert L. Forbis and N. A. Gonzales shipped fluorspar to steel plants and iron foundries from the Polly Ann mine in Greenlee County and the Fluxore claims in Pima County, respectively.

California.—Some Nevada fluorspar was ground at the plant of the Industrial Minerals & Chemical Co. at West Berkeley and shipped to the ceramic trade during 1941. The ground fluorspar has been credited to Nevada in the statistics.

Colorado.—Shipments of fluorspar from Colorado mines totaled 15,566 short tons in 1941 compared with 11,032 tons in 1940 and have been exceeded only in 1917 and 1918. Most of the 1941 shipments went to steel plants, but some went to iron foundries and to ferro-alloy, cement, glass, and enamel plants. Production in 1941 came from Boulder, Chaffee, Custer, Jackson, and Mineral Counties, but mines in Chaffee and Mineral Counties supplied 96 percent of the State total.

After considerable experimental work and a small production of fluxing-gravel fluorspar, Harry M. Williamson reports that his mill in Boulder County has been remodeled to produce acid-grade fluorspar and that the shaft at his Emmett mine was sunk about 175 feet during 1941. The General Chemical Co., which acquired the Chancellor, Yellow Girl, and Burlington mines in Boulder County in 1940, is rehabilitating these mines and building a flotation plant, which is expected to begin production in May 1942. The American Fluorspar Corporation did considerable development work at its mines in Chaffee County, and a flotation mill to be operated by the Fluorspar Processing Co. is being built on its property. The Colorado Fluorspar Corporation at Salida, in addition to a large increase in production of fluxing gravel and foundry lump fluorspar in 1941, shipped about 900 tons of flotation concentrate to the glass and enamel trades. The Western Feldspar Milling Co. shipped 731 tons of ground fluorspar to the glass trade in 1941. The Western Fluorspar Corporation in late 1941 leased the property of the Colorado Fluorspar Corporation (not affiliated with the Colorado Fluorspar Corporation, Salida) near Northgate, Jackson County; it has been rehabilitating the mine and remodeling and enlarging the mill, which is hoped to be in production in July 1942. Three 5-cell Harz jigs are being built, trommel screens are being replaced by vibrating screens, and Diesel power is being substituted for steam.

Illinois.—Approximately 248,000 short tons of fluorspar-bearing material, equivalent to 135,000 tons of finished fluorspar, were mined in 1941 compared with about 213,000 tons, equivalent to 111,000 tons of finished fluorspar, in 1940. Of the finished fluorspar produced in 1941, it is estimated that 71,000 tons were from mines where the fluorspar occurs in veins, chiefly fault fissures, and 64,000 tons from mines where the fluorspar occurs in flat-lying tabular masses, locally called blanket formations. Of the fluorspar produced in Illinois in 1941, about 97 percent came from Hardin County and 3 percent from Pope County.

Fluorspar-bearing material milled in Illinois in 1941 totaled 248,000 tons, from which about 135,000 tons of finished fluorspar were recovered—a ratio of 1.84:1. Considerable fluorspar of Kentucky origin is milled in Illinois, but the finished fluorspar so recovered, as well as that shipped, is credited to Kentucky in the statistics.

Shipments from Illinois totaled 133,333 tons in 1941 compared with 104,698 tons in 1940; 39,918 tons were shipped by river or river-rail to consumers in 1941 compared with 36,756 tons in 1940. Shipments from Illinois were larger in 1941 than in any year except 1917, when they totaled 156,676 tons.

The Argo, Blue Diggings, Cave in Rock, Crystal, Daisy, W. L. Davis, Deardorff, Hamp, Hillside, Humm, Lead Hill, Midway-Air Shaft, North Boundary, Rosiclare, Stewart, and Victory mines supplied about 85 percent of the total finished fluorspar produced in Hardin County in 1941; the remainder of the county production came from many mines and prospects, including the Big Creek, Boundary Shaft, Cooper, Diamond, Dimick, DuBois, Eureka No. 4 and No. 5, Indiana, Kamm, Pell, Preen, Sheldon, Spar Mountain, Twitchell, and Wall.

The Fluorspar Products Corporation operated the Lead Hill, Stewart, and Twitchell mines and also milled purchased ore from various properties. Shipments were 114 percent greater than in 1940. A 5-cell Bendelari jig was added to the mill, and a change from steam to electricity is reported to have effected much smoother operation.

The Aluminum Ore Co. produced 27 percent more fluorspar at its flotation plant in 1941 than in 1940; the plant was closed from January 11 to 23, 1941, and during November 1940 because of a strike at its East St. Louis plant, where artificial cryolite and aluminum fluoride are made from fluorspar. The capacity of the flotation plant was enlarged substantially in 1941, and another substantial expansion, which will be completed about July 1, 1942, is now in progress. Additional drying and grinding facilities are also being installed to handle the increased output. Drifting and raising at the Argo mine extended levels down to 700 feet; minor developments were carried out at the Blue Diggings mine; and a vertical shaft to a depth of 300 feet was completed at the Hamp mine.

At the Crystal mine of the Crystal Fluorspar Co. additions were made to the mill between January 1 and March 21 (there was no production during this interval); consequently, output during 1941 was 10 percent less than in 1940. Prospecting and development work included 13,695 feet of churn drilling.

Output of gravel fluorspar and flotation concentrates by Hillside Fluor Spar Mines was 36 and 353 percent, respectively, greater than in 1940. The mill feed came chiefly from the Hillside mine at Rosi-

clare, Ill., Keystone and Ada Florence mines near Marion, Ky., and tailings from previous milling operations.

The Rosiclare Lead & Fluorspar Mining Co. operated the Boundary Shaft, Daisy, Eureka No. 4 and No. 5, Midway-Air Shaft, North Boundary, and Rosiclare mines in 1941; production was at about the same rate as in 1940. Output at its flotation plant, however, was about five times that in 1940. The flotation plant has been described by Edwards.[4] The Rosiclare mine, which had been flooded since January 1924, resumed production in 1941; it has now been cleaned out to the 700-foot level, where development work will soon be initiated. Unwatering the Rosiclare mine has been described by Cronk [5] and the mine pumping plant and new power plant by Edwards.[6] The company did considerable development work to determine the extension of the Argo fault on its property; a 1,000-foot crosscut has been driven from the 600-foot level of the Daisy mine west to intersect the Argo fault.

The Victory mine of the Victory Fluorspar Mining Co. produced 187 percent more fluorspar than in 1940.

The Cave-in-Rock Spar Co. operated its No. 1 and No. 2 mills on ore from its own mines, as well as on purchased ore; production of finished fluorspar was substantially greater than in 1940. No. 1 mill was leased to and operated by the Continental Fluorspar Co. for a 4-month period and milled purchased ore. The company did some developing at the Pell and Teems properties and made improvements in both mills.

The flotation mill of the Mahoning Mining Co. operated at capacity in 1941, and production of fluorspar concentrates was 50 percent greater than in 1940. The mill feed comprised ore from the W. L. Davis and Deardorff mines and a small quantity of purchased ore. Of the fluorspar shipped in 1941, 86 percent was acid-grade and 14 percent pelletized gravel; 25 percent of the acid-grade was shipped for foreign consumption The flotation plant has been described by Trauffer.[7]

Ralph E. Jones and J. R. Ginn completed small mills near Rosiclare and Elizabethtown, respectively, in 1941. The Big Creek Fluorspar Co. also completed a mill near Rosiclare in 1941; equipment includes air tables, an innovation in fluorspar milling.

The Atlas Fluorspar Co. operated its jig mill on purchased ore and did some custom milling. The mill was run during the latter part of 1941 by the Crown Fluorspar Co., which also milled purchased ore and reported exploration and development work at properties it has under lease.

Production at the Humm mine, operated by C. C. Mackey, was about the same as in 1940. Beecher Williams reported sinking a 160-foot shaft on the Humm property in 1941.

The Douglas, Lost 40, and Roberts mines were the chief producers of fluorspar in Pope County during 1941. Knight, Knight & Clark operated its mill on ore from the Douglas mine. Production at the Lost 40 mine was sold to local mills for milling. The Kentucky

[7] Trauffer, W. E., Fluorspar Separated by Flotation at New Plant in Illinois-Kentucky Field: Pit and Quarry, May 1941, vol. 33, pp. 39–42.

Fluor Spar Co. acquired the Knight mine on June 28 and renamed it the Roberts mine. It was equipped and brought into production the latter part of 1941.

Kentucky.—Production of fluorspar (expressed in terms of finished product) in Kentucky was about 136,000 short tons in 1941 compared with 107,000 tons in 1940. Shipments, which exceeded the previous all-time record of 1940 by 37 percent, were 142,862 tons compared with 103,939 tons in 1940; of the 1941 total, 34,698 tons were shipped by rail or river-rail to consumers compared with 29,672 tons in 1940.

Production in Caldwell County, totaling about 8,000 tons, came chiefly from the H. & W., Hollowell & Hobby, Marble, McNeely, and Tyrie mines. A large increase in production was reported at the Hollowell & Hobby mine, which was acquired by the New York & Kentucky Mining Co. in 1940.

The Marble mine was leased on June 19 by the Marble Mining Co., which also leased the Crook mill at Crider. A 96-foot shaft was sunk at the mine; and the mill, which had been idle for many years, was rehabilitated.

Production at the McNeely mine, operated by J. D. Summers & Co., was discontinued in May, owing to exhaustion of known ore bodies.

Production in Crittenden County, totaling 105,000 short tons, came chiefly from the Ada Florence, Bachelor, Davenport, Gillis, Keystone, Pigmy, Summers, Tabb, and Watson (Eagle) mines, which contributed 85 percent of the county total. Most of the remainder came from many smaller mines (including the Beard, Blue, Brown, Dyke, Haffaw, Mary Belle, Memphis, Pogue, Susie Beeler, and Watkins) and from numerous prospects; some was reclaimed from mill ponds, waste dumps, and old workings of abandoned mines.

The Beard, Brown, Cross, Haffaw, Mary Belle, Memphis, and Susie Beeler mines of the Aluminum Ore Co. were operated by lessees at a greatly reduced rate during 1941. The surface plants at these mines, as well as those at other mines of the company in Kentucky, have been removed, and its mill at Marion has discontinued operation. The mill site will be used for the accumulation of fluorspar purchased from local contractors. The company operates mines and a flotation mill near Rosiclare, Ill., where operations will proceed at a greatly increased rate.

The Watson mine of the Eagle Fluor Spar Co. was operated on a two-shift basis, and the output of finished fluorspar was 13 percent larger than in 1940.

R. J. Forester's mill handled ore from his Summers mine and some purchased ore, recovering 37 percent more finished fluorspar than in 1940.

The Tabb mines and mill of the United States Coal & Coke Co. produced 19 percent more finished fluorspar than in 1940; shipments, however, were 4 percent less. In addition to the production from the Tabb mines, a contractor made a small output on the company property. Some purchased ore was also treated in the company mill.

The Kentucky Fluor Spar Co., which operates a mill a short distance south of Marion, did the largest volume of business in its history; sales were 35 percent greater than in 1940. In 1941 the com-

pany operated the C. R. Babb and Ellis mines in Livingston County, Ky., and the Roberts mine in Pope County, Ill.; about half the company supply came from these mines. The remainder was purchased chiefly from the Blue, Dyke, Hollowell & Hobby, McNeely, Nancy Hanks, and Watkins mines in Kentucky and the Humm and Kamm mines in Illinois.

The Ada Florence and Keystone mines of Hillside Fluor Spar Mines were operated at a substantially increased rate in 1941. Although the fluorspar from these mines is finished at the company mill at Rosiclare, Ill., production and shipments are credited to Kentucky in the statistics.

A newly discovered ore body of considerable length and depth was developed at the Pigmy mine of the Pigmy Corporation in 1941. Production was about double that in 1940.

Exploration by crosscut at the 130- and 260-foot levels of the Davenport mine, both in the vicinity of the main shaft, disclosed at least two hitherto unknown ore bodies east of those already worked; they promise considerable tonnage. Production was about the same as during 1940.

The Pogue mine was leased in July 1941 by the Marble Mining Co., which cleaned out an old filled-in abandoned shaft and retimbered it to the 175-foot level. Washing equipment was installed at the mine. A small tonnage of fluxing-gravel fluorspar was produced in 1941. During October the company also leased the Sullinger mine and installed washing equipment.

In 1941 the Delhi Fluorspar Corporation did considerable development work at its Bachelor mine and installed a new double log washer and bath house. Production was about double that in 1940.

The capacity of the mill of the Howard Easley Corporation was enlarged to handle one-third more tonnage. This corporation does not operate any mines but does milling upon a custom basis for others. It also purchases fluorspar from many mines and prospects, milling some of this before shipment.

In Livingston County 23,000 short tons of finished fluorspar were produced in 1941 compared with 21,000 tons in 1940. Of the county total in 1941, the C. R. Babb, Ellis, Mineral Ridge, and Nancy Hanks mines and the jig plant reclaiming fluorspar from Klondike tailings supplied about 91 percent.

Output at the C. R. Babb and Ellis mines of the Kentucky Fluor Spar Co. was 25 and 27 percent, respectively, greater than in 1940. The company also made a small production at the Wright mine. The shaft at the C. R. Babb mine was sunk 100 feet, making a total depth of 450 feet, where levels are being driven along the vein; the power plant at this mine was improved and enlarged. The lease on the Wright mine was acquired by C. W. Haynes, who sank a 50-foot shaft and mined a small tonnage of mixed fluorspar-barite ore.

Production at the Nancy Hanks mine, operated by the Haynes Fluorspar Co., was 17 percent less than in 1940; sales, however, were 11 percent greater.

The Mineral Ridge Fluorspar Co. produced and shipped fluorspar from the Mineral Ridge mine in 1941.

The Klondike mine made no production in 1941, but the remainder of the mine stock pile was shipped.

Shipments by Butler & Moodie, who operate a jig plant reclaiming fluorspar from Klondike tailings, were considerably larger than in 1940.

In the central Kentucky district a small carload of fluorspar was shipped from the Faircloth mine in Woodford County, near Wilmore.

Nevada.—Shipments of fluorspar from Nevada in 1941—8,967 short tons—exceeded the previous all-time record of 5,803 tons in 1940. Most of the 1941 total went to steel mills and hydrofluoric-acid plants.

The chief producing mine in Nevada in 1941 was the Baxter in Mineral County, operated by V. S. Baxter, where some development work was done. The other active mine was the Daisy in Nye County, operated by J. Irving Crowell, Jr. New equipment was installed at the Daisy mine and mill to increase productive capacity; a flotation unit was also installed but did not operate.

New Mexico.—Production of fluorspar in New Mexico also established a new record in 1941. Shipments from New Mexico, Arizona, and Texas were 19,089 short tons and comprised flotation concentrates (which went chiefly to ceramic and hydrofluoric-acid plants), metallurgical grade (which went chiefly to steel plants), and acid grade (which went to hydrofluoric-acid plants).

Production in New Mexico came from Grant, Hidalgo, Luna, Sierra, and Valencia Counties.

Output at the flotation mill of the Indian Metals Co. at Lordsburg gained 17 percent over 1940. The ore milled came from many properties, but the greater part came from the Howard mine in Luna County and the Shrine mine in Grant County.

The flotation mill of the General Chemical Co. at Deming was operated on a substantially larger scale than in 1940. Most of the ore milled was purchased from producers in New Mexico and Arizona.

The gravity-flotation plant of the Non-Metallic Corporation at Silver City was not operated in 1941.

P. L. Grattan is remodeling his flotation plant at Deming; meanwhile, ore was produced at his mine in Luna County and stock-piled at the mill.

The Howard mine in Luna County, operated by D. F. McCabe, was the largest producer in New Mexico in 1941. About one-third of the output was shipped to steel plants and two-thirds to the flotation plants at Deming and Lordsburg.

The Navajo mines in Valencia County, which have been under development for some time by Navajo Fluorspar Mines, became an important producer in 1941. Production comprised chiefly metallurgical gravel fluorspar shipped to steel mills, but a small quantity of acid grade was shipped to hydrofluoric-acid plants. From July through December 1941 shipments averaged about 700 tons monthly and in January 1942 totaled 1,250 tons. Four tunnels above water level are in active operation on two veins. Although one of the veins is reported to yield acid grade by careful sorting, the output is blended with the lower-grade product from the other vein to make fluxing grade. The mining property is in the Zuni Mountains about 25 miles south of Grants, the shipping point. Ore from the mine is trucked to the mill at Grants, where it is dumped into a hopper that is carried by elevators to a 400-ton bin, which discharges through an automatic feeder to the crusher, rolls, and washer. After washing, the ore is put through screens before going to two 4-cell Bendelari jigs and a smaller Harz jig; some of the fines pass over a concentrating table. The

finished fluorspar is carried by another set of elevators to a bin for loading into cars. Additions to the mill to produce acid-grade fluorspar are contemplated.

Small outputs were made at the Montezuma, Mirabal, and Porter mines, also in Valencia County.

Texas.—In the course of surface prospecting at the Horse Shoe prospect near Hot Wells, Hudspeth County, U. B. Melton produced and shipped a small tonnage of fluorspar to the flotation plant at Deming, N. Mex. It is planned to sink a shaft at the property in 1942.

Utah.—Shipments of fluorspar from Utah were 748 short tons in 1941 compared with 142 tons in 1940, all from the Fred Staats mine in Beaver County. Development work under way at this mine is expected to result in a much larger output in 1942. The Western Fluorite Co. continued development work at its properties in Beaver County and made a trial run at its mill.

Washington.—Crushing, screening, and concentrating equipment was installed at the Mitchem mine in Ferry County, and new stopes were opened in the mine. Two cars of fluorspar were shipped in 1941. This mine was reopened in 1940 and shipped a car of fluorspar, but the report was received too late for inclusion in the statistics for that year; consequently, it has been included in the total for 1941.

IMPORTS AND SHIPMENTS FOR FOREIGN CONSUMPTION

Imports of fluorspar for consumption in the United States during the 9 months January to September 1941 were 7,311 short tons (1,303 tons containing more than 97 percent and 6,008 containing not more than 97 percent calcium fluoride) valued[8] at $73,099. Publication of foreign trade statistics was suspended beginning October 1, 1941. Imports during the year 1940 were 11,873 tons (3,052 containing more than 97 percent and 8,821 containing not more than 97 percent calcium fluoride) valued[8] at $142,931. The value assigned to the foreign fluorspar in 1941 averaged $10 a ton. The cost to consumers in the United States also includes duty, loading charges at the docks, ocean freight, insurance, consular fee, and freight from docks to consuming plants. The duty on fluorspar containing not more than 97 percent calcium fluoride is $7.50 a short ton and on fluorspar containing more than 97 percent calcium fluoride $3.75 a short ton.

Fluorspar imported for consumption in the United States in 1941 (January to September, inclusive), by countries and customs districts

Country and customs district	Containing more than 97 percent calcium fluoride		Containing not more than 97 percent calcium fluoride		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
Mexico:						
Laredo	69	$863			69	$863
Maryland			1,621	$14,704	1,621	14,704
New York	1,234	21,951			1,234	21,951
Philadelphia			1,315	12,777	1,315	12,777
	1,303	22,814	2,936	27,481	4,239	50,295
Spain: Philadelphia			3,070	22,772	3,070	22,772
United Kingdom: Rochester			2	32	2	32
	1,303	22,814	6,008	50,285	7,311	73,099

[8] As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise * * * is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

The foregoing imports for 1941 comprised 82 percent metallurgical gravel fluorspar and 18 percent acid-grade fluorspar. The former was imported from Mexico, Spain, and United Kingdom and the latter from Mexico.

The following table, compiled from data furnished to the Bureau of Mines by importers, shows the quantities of imported fluorspar delivered to consumers in the United States in 1940 and 1941 and the selling price at tidewater (duty paid), irrespective of the year of importation into the United States; it differs from the preceding table, which shows the quantities received in the United States during the first 9 months of 1941. The quantities in the following table are based upon the actual outturn weights ascertained by sworn weighers and represent the weights on which duty was paid and entries were liquidated.

Imported fluorspar delivered to consumers in the United States, 1940–41, by uses

Use	1940			1941		
	Short tons	Selling price at tidewater, including duty		Short tons	Selling price at tidewater, including duty	
		Total	Average		Total	Average
Steel	9,275	$204,342	$22.03	6,102	$143,863	$23.58
Glass and enamel	11	361	32.82			
Hydrofluoric acid	1,634	44,845	27.44	1,418	38,760	27.33
Miscellaneous	4	160	40.00	69	1,380	20.00
	10,924	249,708	22.86	7,589	184,003	24.25

Producers of fluorspar reported shipments of 12,184 short tons of fluorspar valued at $277,782 in 1941 for foreign consumption compared with 8,482 tons valued at $178,467 in 1940.

Fluorspar reported by producers as shipped from the United States for foreign consumption, 1937–41

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average			Total	Average
1937	456	$9,091	$19.94	1940	8,482	$178,467	$21.04
1938	788	9,061	11.50	1941	12,184	277,782	22.80
1939	2,976	74,443	25.01				

WORLD PRODUCTION

The following table shows world production of fluorspar by countries from 1937 to 1941, insofar as statistics are available. Because of Government restriction on the publication of statistics for many countries, few figures for 1940 and 1941 are available. However, as the output of steel and aluminum increased greatly in many countries, no doubt world production of fluorspar also gained in 1940 and 1941. Despite the fact that fluorspar is produced in about 20 countries, the United States, Germany, U. S. S. R., United Kingdom, and France normally supply about four-fifths of the world total.

World production of fluorspar, 1937–41, by countries, in metric tons [1]

[1] In addition to countries listed, China and Mexico produce fluorspar but data of output are not available.
[2] Railway shipments.
[3] Data not available.
[4] Exports.
[5] January to June, inclusive.
[6] Estimated.
[7] Estimate included in total.

Canada.—The North American Molybdenum Corporation has erected a new head frame at the Madoc property, and the old shaft has been retimbered to its bottom level at 80 feet; plans call for deepening the shaft to 150 feet and establishing a main level at that horizon.[9] The company has started mining operations, and material is being stock-piled for shipment.[10]

China.[11]—The Central China Mining Co. (Sino-Japanese subsidiary of the Japanese semiofficial Central China Development Co.) announced in September 1940 that it would open fluorite mines in northern Chekiang Province. The Japan Iron Mining Co. is stated to have been producing 20,000 tons from mines in that region, but the Central China Mining Co. plans call for an additional production of 200,000 tons annually, the entire output to be exported to Japan.

Chosen.[12]—The Chosen Development Co. is reported to have completed arrangements for the purchase of the Chosen Fluorspar Co., capitalized at approximately $42,192, and for the operation of the mine and sorting mill at Talden, South Chusei Province.

Mexico.[13]—Installation of a 500-ton mill is being completed at the La Azul fluorspar mine, Taxco, Guerrero.

Newfoundland.—Shipments of fluorspar from Newfoundland in 1941 were 12,766 short tons, comprising 4,448 tons of acid grade and 8,313 tons of fluxing grade. Shipments were 16,201 tons in 1940. The decline in shipments was due to labor troubles.

According to Canadian Chemistry and Process Industries:[14]

[9] Northern Miner, May 22, 1941, vol. 27, No. 9, p. 23.
[10] Northern Miner, October 2, 1941, vol. 27, No. 28, p. 5.
[11] Foreign Minerals Quarterly, October 1941, vol. 4, No. 2, p. 13.
[12] Foreign Commerce Weekly, August 16, 1941, vol. 4, No. 7, p. 36.
[13] Engineering and Mining Journal, October 1941, vol. 142, No. 10, p. 92.
[14] Canadian Chemistry and Process Industries, January 1941, vol. 25, No. 1, p. 15.

No attempt has been made to estimate the reserves [of fluorspar] of the [St. Lawrence] district, but the St. Lawrence Corporation of Newfoundland, Ltd., has obtained its production from one vein along a length of 1,200 feet on the 50-foot level and has, among other veins, one with a surface length of 5,500 feet, with widths varying from 2 to 24 feet. Another company, Newfoundland Fluorspar, Ltd., a subsidiary of Aluminum Co. of Canada, Ltd., has been doing exploration and development work for the past 3 years, having drifted for 1,800 feet on the 150-foot level, with crosscuts every 100 feet showing widths from 10 to 35 feet.

Union of South Africa.—Figures on production of fluorspar in the Union of South Africa in 1941 are available for only the first 6 months of the year and totaled 2,024 short tons; shipments during this period were 2,765 tons, of which 1,291 tons were exported to Japan, 280 tons to India, and 43 tons to Northern Rhodesia, and 1,151 tons were sold to local consumers. Production in the year 1940 was 8,180 short tons; shipments were 6,995 tons, of which 4,621 tons were exported to Japan, 103 tons to India, 19 tons to United Kingdom, 6 tons to Southern Rhodesia, and 3 tons to Belgian Congo, and 2,243 tons were sold to local consumers.

CRYOLITE

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. Gibbs [15] has described the mine at Ivigtut, the grades of ore produced, methods of processing and purification, and various uses of cryolite.

A considerable proportion of the cryolite used in the United States is made from fluorspar. According to Frary: [16]

The fluorspar is treated with sulfuric acid to produce hydrofluoric acid, and this is neutralized with the proper amounts of soda ash and aluminum hydrate to produce the cryolite, which is a double fluoride of sodium and aluminum (Na_3AlF_6). The artificial cryolite is quite satisfactory and, in fact, considerably lower in objectionable impurities than the natural cryolite usually used. There would be no serious difficulty in getting along with the artificial product if the supply of natural cryolite from Greenland is shut off.

The chief uses of cryolite are in the metallurgy of aluminum, in the manufacture of glass and enamels, and in insecticides.

Artificial cryolite is manufactured by the Aluminum Ore Co. at East St. Louis, Ill.; the capacity of the plant was enlarged substantially in 1941. A small quantity of artificial cryolite was made in a pilot plant by the Pennsylvania Salt Manufacturing Co. in 1941, and construction of a commercial plant is under consideration.

Imports.—The following table shows imports of cryolite into the United States in 1940 and in the first 9 months of 1941.

Cryolite (natural and artificial) imported for consumption in the United States, 1940–41, by countries

Country	1940		1941 (Jan.-Sept.)	
	Long tons	Value	Long tons	Value
Canada			4	$1,118
France	20	$3,300		
Germany	20	3,713		
Greenland	25,818	1,322,775	14,924	823,850
	25,858	1,329,788	14,928	824,968

FELDSPAR

By Robert W. Metcalf

SUMMARY OUTLINE

SUMMARY

Paralleling record production and shipments of glass containers, both crude and ground feldspar in 1941 again established new production (sales) highs, despite curtailment of new home construction during the last quarter of the year. Sales of crude spar rose to 338,860 long tons, valued at $1,519,456; thus tonnage was 17 percent higher and value 19 percent higher than in 1940. Sales of ground spar in 1941 totaled 354,417 short tons, a 24-percent increase over the 285,713 tons reported for 1940. Total values of crude and ground feldspar in 1941 were 19 and 23 percent, respectively, above 1940 levels; these values, however, were 5 percent less for crude spar and only 0.2 percent greater for ground spar than in 1926, the year of highest realization for crude output.

Salient statistics of the feldspar industry in the United States, 1940–41

	1940	1941	Percent of change in 1941

[1] Figures cover January to September, inclusive.

Imports of crude feldspar (all from Canada) during the first 9 months of 1941 totaled 8,934 long tons valued at $56,731 compared with 12,522 tons, $80,274, during the full year 1940.

California, Colorado, Maine, New Hampshire, North Carolina, South Dakota, and Wyoming each made a substantially increased output of crude feldspar in 1941. Colorado, New Hampshire, and South

Dakota produced record tonnages, and the North Carolina output reached 100,000 tons for the first time since 1936. Production of ground spar showed large increases in California, New Jersey-Connecticut, and North Carolina-Tennessee, with record tonnages in both Colorado and South Dakota.

DOMESTIC PRODUCTION

In accordance with the usual practice in the industry, crude feldspar is reported in long tons of 2,240 pounds and ground feldspar in short (net) tons of 2,000 pounds, although some leading producers report sales of crude spar in short tons.

Crude feldspar.—Output of crude feldspar reached a new high in 1941, rising to 338,860 long tons or 17 percent above the former record year 1940. The total value ($1,519,456) in 1941 was 19 percent above that in 1940 but 5 percent less than in the record year 1926.

Texas reported output of crude spar in 1941 for the first time and Massachusetts for the first time since 1910; otherwise, spar was mined during 1941 in the same States that produced in 1940. Three States made record outputs in 1941—South Dakota (59,015 long tons), New

Hampshire (52,219 tons), and Colorado (42,326 tons). North Carolina's output increased about one-fourth; it represented 30 percent of the national total compared with 27 percent in 1940 and 35 percent in 1937. California's output jumped 65 percent to 4,464 tons. Maine, with a production of 22,566 tons, mined more spar than in any year since 1930. The accompanying map (fig. 1) shows the geographical distribution of feldspar mines and grinding plants in the United States.

Average sales realization per long ton for crude feldspar increased about 3 percent to $4.48 in 1941 from $4.37 in 1940. Average values reported for North Carolina, Maine, Virginia, and Connecticut were somewhat higher than in 1940, whereas those for South Dakota and New Hampshire were virtually the same as in 1940. Colorado showed a small decrease. Averages per ton for selected States in both years (1940 in parentheses) follow: North Carolina, $5.52 ($5.38); Maine, $5.17 ($4.61); Virginia, $5.58 ($5.37); South Dakota, $2.89 ($2.88); New Hampshire, $3.84 ($3.86); and Colorado, $3.49 ($3.62).

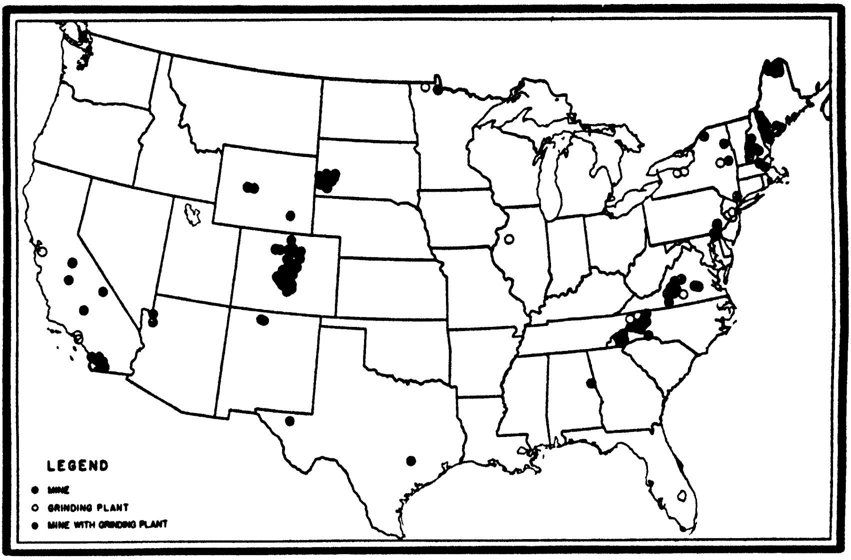

FIGURE 1.—Geographical distribution of feldspar mines and grinding plants in the United States.

Ground feldspar.—Ground feldspar sold by merchant mills in 1941 again established a new high, rising to 354,417 short tons or 24 percent above the former record year 1940. The total value in 1941 ($3,782,603) exceeded slightly (0.2 percent) that reported for 1926, the previous record year for total realization. Colorado and South Dakota together supplied 34 percent of the total ground spar sold or used during 1941 compared with 35 percent in each of the 3 years immediately preceding and 30 percent in 1937. North Carolina-Tennessee, although showing a 22-percent increase over 1940, furnished about the same percentage (27 percent) of the total sales in 1941 as in 1940, compared with about 29 percent in both 1938 and 1939 and 32 percent in 1937. Only 2 percent of the total sales of ground spar from United States mills in 1941 was of Canadian origin, compared with 3 percent in 1940, 4 percent in both 1938 and 1939, and 6 percent in 1937.

Colorado in 1941 rose to first place in output (tons) of ground feldspar and produced more than in any year in its history. The output was 61,141 short tons valued at $387,338 in 1941, or 38 percent more in quantity than in 1940. South Dakota, again with a record tonnage, followed closely with 59,581 tons and $407,454. Tennessee, New Hampshire, and North Carolina ranked next in order. Output from Tennessee and North Carolina combined (95,391 tons) was the largest since 1929. Sales by mills in other States increased from 1940 to 1941, as follows: Arizona, 23 percent; California, 55 percent; Maine, 1 percent; New Jersey and Connecticut combined, 21 percent; New York, 39 percent; and Virginia, 60 percent. Figure 1 shows the distribution of feldspar grinding plants in the United States.

Ground feldspar sold by merchant mills [1] in the United States, 1937–41

Year	Active mills	Domestic			Canadian			Total	
		Short tons	Value		Short tons	Value		Short tons	Value
			Total	Average		Total	Average		
1937	31	263,387	$3,187,185	$12.10	15,885	$299,556	$18.86	279,272	$3,486,741

1940	29	277,612	2,912,470	10.49	8,101	153,012	18.89	285,713	3,065,482
1941	29	347,092	3,646,404	10.51	7,325	136,199	18.59	354,417	3,782,603

[1] Excludes potters or others who grind for consumption in their own plants

The average sales realization for ground feldspar in 1941 declined further to $10.67 per ton from $10.73 in 1940 and $11.04 in 1939. Average values for individual States also were generally slightly less in 1941 than in earlier years—ranging from $6.34 to $17.92 in 1941, $6.38 to $17.96 in 1940, and $6.42 to $18.01 in 1939. Average values for specified States in 1941 follow: Colorado, $6.34; South Dakota, $6.84; California, $11.84; North Carolina-Tennessee, $12.37; Maine, $13.72; and New Jersey and Connecticut combined, $17.92.

Quoted prices on ground feldspar, however, remained unchanged throughout 1941 and into 1942, according to Engineering and Mining Journal Metal and Mineral Markets. As of January 29, 1942, quotations were reported as follows: Potash spar, f. o. b. North Carolina, 200-mesh, white, $17 per ton in bulk; soda spar, $19 per ton; potash spar, f. o. b. Maine, 200-mesh, white, $17 per ton in bulk; North Carolina granular glass spar, 20-mesh, white, f. o. b., $12.50 per ton in bulk; semigranular, $11.75 per ton; Virginia feldspar, No. 1, 230-mesh, $18, 200-mesh, $17; No. 17 glassmakers' spar, $11.75, No. 18 glassmakers' spar, $12.50; and enamelers' spar, $14 to $16 (quotations upon Spruce Pine, N. C., or Keene, N. H., basis).

CONSUMPTION AND USES

Crude feldspar.—Most crude feldspar is sold to merchant mills, which obtain their supply from a number of mines or localities, stockpile and sort it according to grade and source, blend and grind it to required purity and fineness, and sell the ground product. However, some pottery and enamel manufacturers purchase part of their feldspar supply crude and grind it with their own equipment as needed; at least two sanitary-ware manufacturers mine and grind spar for their own use. Makers of soap, cleansers, and sweeping compounds also mine crude feldspar or purchase it—chiefly in New England, Virginia, and North Carolina—and, after grinding or other processing, utilize it as an abrasive in their products. Manufacturers of artificial teeth each year use a small tonnage of carefully selected crude material, which is sold at a substantial premium over No. 1 grade commercial feldspar.

Ground feldspar.—Over 95 percent of the ground feldspar sold by merchant mills in the United States is consumed in ceramics in the manufacture of glass, pottery, and enamel. The quantity consumed in 1941 by the glass industry—principal marketing outlet—totaled 182,878 short tons, an increase of 22 percent over 1940. The proportion of total sales used in glass, however, declined slightly to 51.6 percent from 52.4 percent in 1940 and 53.4 percent in 1939; these figures exclude nepheline syenite, "aplite", and other sources of alumina used in glass-making, the competitive importance of which is increasing steadily. Sales (127,140 tons) to potteries in 1941 increased 22 percent over 1940, and those (34,841 tons) to enamel manufacturers rose 32 percent. Ground spar sold for use in soaps and abrasives—a minor sales outlet for material ground by merchant mills—decreased sharply from 1940 but amounted to nearly twice the 1939 figure. The remainder of the ground spar sold by merchant mills was utilized for purposes not specified and for various ceramic uses other than glass, pottery, or enamel.

Ground feldspar sold by merchant mills in the United States, 1939–41, by uses, in short tons

Use	1939		1940		1941	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Ceramic:						
Glass	138,336	53.4	149,623	52.4	182,878	51.6
Pottery	87,209	33.7	104,586	36.6	127,140	35.9
Enamel	28,356	10.9	26,420	9.3	34,841	9.8
Other ceramic uses	2,132	.8	649	.2	563	.2
Soaps and abrasives	770	.3	2,682	.9	1,490	.4
Other uses	2,391	.9	1,753	.6	7,505	2.1
	259,194	100.0	285,713	100.0	354,417	100.0

Shipments of ground spar from merchant mills into the principal consuming States were larger in 1941 than in 1940 for all destinations shown separately. Pennsylvania, receiving 54,534 short tons, topped Ohio by a narrow margin and was the largest consuming State; each of these States contributed about 15 percent of the total. Next in order were Illinois (receiving 13 percent), New Jersey (13 percent), Indiana (11 percent), West Virginia (8 percent), New York (5 percent), and Wisconsin, California, and Tennessee combined (9 percent). Shipments to "Other destinations" in 1941 (comprising 11 percent of the total) included sizable tonnages to Louisiana, Maryland (incomplete returns indicate an approximate consumption of 15,000 tons), Michigan, Minnesota, Mississippi, and Oklahoma, and smaller shipments to some 17 other States, District of Columbia, Hawaii, and Canada.

Ground feldspar shipped from merchant mills in the United States, 1940–41, by destinations, in short tons

Destination	1940	1941	Destination	1940	1941
California	7,897	10,444	Tennessee	5,911	9,697
Illinois	32,811	44,573	West Virginia	21,889	29,916
Indiana	28,634	39,620	Wisconsin	6,967	10,517
New Jersey	42,381	44,249	Other destinations [1]	27,721	40,271
New York	13,236	18,326			
Ohio	50,835	52,270		285,713	354,417
Pennsylvania	47,431	54,534			

[1] Arkansas, Colorado, District of Columbia, Hawaii, Kentucky, Louisiana, Maryland (estimated at 15,000 tons in 1941), Michigan, Minnesota, Mississippi, Missouri, Oklahoma, Puerto Rico, South Carolina, and other States for which shipments cannot be segregated. Small shipments to Canada, England, and Mexico also included.

NEPHELINE SYENITE

Industrial interest in nepheline syenite for ceramic purposes continued active, with expanding sales for general pottery use. The glass industry, however, remains the chief consumer of this comparatively recently used raw material. Imports of crude nepheline syenite from Canada into the United States in the first 9 months of 1941 amounted to 23,773 short tons, valued at $74,429; 27,888 tons, valued at $87,162, were received during the entire year 1940. In addition, 718 short tons of ground nepheline syenite (all from Canada), valued at $7,448, were imported during the first 9 months of 1941 compared with 6 tons, valued at $25, in the entire year 1940.

Market quotations on ground nepheline syenite, f. o. b. Rochester, N. Y., as reported in Ceramic Industry, February 1942, were as follows: Glass grade, $12 per (short) ton, and pottery grade, $15.50 per ton.

Research was being continued in the Canadian Bureau of Mines laboratories on the feasibility of treating nepheline syenite for the recovery of alumina and alkalies, the former as a substitute for bauxite in the production of aluminum. Field explorations and drilling of nepheline syenite bodies were undertaken in the Bancroft district in an effort to locate deposits of higher grade and greater uniformity.

A detailed description of nepheline syenite, giving its composition and properties, as well as its advantages in making glass, various types of pottery and enamels, was published at the beginning of 1942.[1]

Baggs [2] has described a number of bodies and glazes containing nepheline syenite. Nogai and Yamabe [3] made studies of special glasses containing large amounts of alumina and magnesia, using nepheline or nepheline syenite as raw materials. Priest [4] discussed the use of nepheline syenite in enamels for cast iron. According to Koenig,[5] the greater fluxing power of nepheline syenite tested in hotel chinaware bodies in place of potash feldspar allowed a lower firing temperature, reduced the amount of principal flux, and reduced or eliminated the use of auxiliary flux. A study of electrical porcelain fluxed with nepheline syenite rather than potash feldspar has indicated an earlier vitrification, about the same firing shrinkage at maturing temperatures, an equal or greater transverse strength, dense well-vitrified bodies, and similar thermal expansion.[6]

APLITE

The mine and nearby mill of Dominion Minerals, Inc., Piney River, Va., producing "aplite" since 1938, were described by Trauffer.[7] "Aplite," a complex silicate rock composed chiefly of the four minerals albite, microcline, sericite, and zoisite, is used as a source of alumina in the manufacture of glass containers and more recently for flat glass and glass fibers. Production has increased steadily each year. New equipment added during 1941 included two additional magnetic separators. An average analysis of "aplite" from Nelson County, Va., supplied by V. V. Kelsey, president, Dominion Minerals, Inc., follows: Silica (SiO_2), 57.75 percent; ferric oxide (Fe_2O_3), 0.80 percent; alumina (Al_2O_3), 24.00 percent; calcia (CaO), 5.60 percent; alkalies (soda, Na_2O, potash, K_2O), 9.15 percent; loss on ignition, 0.70 percent. A new mill in the same locality was erected during 1941 by the Carolina Mineral Co., Erwin, Tenn., subsidiary of the Consolidated Feldspar Corporation; operation began during the early months of 1942.

TECHNOLOGIC DEVELOPMENTS

A study of engobe composition with varying contents of kaolin, feldspar, and flint [8] indicated that an increase in the proportion of feldspar increases vitrification and crazing of the glaze whereas low feldspar and flint in the engobes cause dullness in the glaze. Experiments with Italian porcelain bodies have shown an increase in refractoriness and viscosity with use of potash feldspar. Substitution of soda feldspar results in a less-transparent porcelain and higher thermal expansion [9] Introduction of too much alumina into enamels as an opacifier in the form of feldspar is not recommended unless a mat enamel is desired owing to the sudden change from glossy to mat when alumina is used.[10] Mixtures of microcline and plagioclase in porcelain ware were studied.[11] According to Norwegian sources, it has been found that labradorite may be used in making aluminum.[12]

The translucency of whiteware bodies containing feldspar or lepidolite, and those containing mixtures of feldspar and lepidolite, was measured, using a photronic cell and spectrophotometer.[13] Bodies composed of mixtures of feldspar and lepidolite were found to be translucent over a greater range of temperature than those containing feldspar or lepidolite alone, although feldspar bodies of equivalent absorption were more translucent than those using lepidolite alone. The spectrophotometer gives a more complete record of the translucency of porcelain, as it may be used to measure the transmittance of ultraviolet, visible, and infrared light. The use of infrared radiation for dehydration of silicic acid derived from feldspar proved definitely superior to present methods [14] and reduced the analytical time materially. Application of the proposed method to other silicates is suggested.

OTHER DEVELOPMENTS

The grinding mill of the Virginia Feldspar Co., Bedford, Va., now taken over by the Carolina Mineral Co., Erwin, Tenn., subsidiary of the Consolidated Feldspar Corporation, was described in detail during the year. Granular glass spar is shipped.[15] The Seaboard Feldspar Co., whose plant at Brookneal, Va., was destroyed by fire, built a new mill at Bedford,[16] in the heart of the principal Virginia feldspar district; the name of the company also was changed to that of the parent firm—the Clinchfield Sand & Feldspar Co.

Possibilities of commercial deposits of feldspar, mica, beryl, and spodumene in the known pegmatite occurrences in Massachusetts were discussed by Billings.[17]

[17] Billings, Marland P., Pegmatites of Massachusetts: Massachusetts Dept. of Public Works and Geol. Survey Coop. Geol. Project Bull. 5, 1941, 22 pp.

A 3-percent increase in freight rates for certain minerals (including feldspar) was approved, to be effective May 15 and until 6 months after the end of the war.[18]

A brief published description of the properties, occurrences, and market classifications of feldspar[19] included lists of producers of crude and ground spar and a selected list of buyers.

Feldspar mining in Canada during 1941 showed little change. Production continued to come chiefly from the two large-scale operators in the Buckingham district, Quebec, and in Bathurst Township, Ontario. The only other concern making important shipments operated near Madawaska in Nipissing district, Ontario, and produced both potash and soda spar.

Large quantities of feldspar are available in the Salem district in southern India, according to a recent survey,[20] but recovery would be difficult. Feldspar is now being mined in Mysore State for the ceramic industry. If the feldspar in the Salem district can be extracted economically, the combined output of the two regions may be adequate for any present or future demand in the neighboring Indian States.

IMPORTS [21]

Feldspar.—Imports of crude feldspar into the United States from January through September 1941 totaled 8,934 long tons valued at $56,731 compared with 12,522 tons valued at $80,274 in the full year 1940. All imports originated in Canada. No receipts of ground feldspar in 1941 were reported.

Feldspar imported for consumption in the United States, 1937–41

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Short tons	Value		Long tons	Value	Short tons	Value
1937	12,956	$91,885			1940	12,522	$80,274		
1938	7,651	56,126			1941 (Jan.–Sept.)	8,934	56,731		
1939	7,460	52,141	2	$54					

Cornwall stone.—Imports for consumption of both unmanufactured and ground Cornwall stone from the United Kingdom, sole source of supply, continued at an active rate during the first 9 months of 1941. Unmanufactured Cornwall stone received during this period totaled 1,931 long tons valued at $20,949 compared with 2,261 tons valued at $20,812 during the full year 1940. Imports of ground Cornwall stone during the first 9 months of 1941 amounted to 182 long tons valued at $2,658 compared with 228 tons valued at $2,758 in the entire year 1940. The average value (foreign market value) per ton for unmanufactured Cornwall stone increased from an average of $9.20 in 1940 to $10.85 in the 1941 period and for ground Cornwall stone from $12.10 to $14.60.

WORLD PRODUCTION

Feldspar sold or used in the United States represents the greater part of the feldspar produced or marketed in the world, according to available data. In addition, a large part—often over half—of the output (shipments) of crude spar from Canadian mines is ground in the United States. Total Canadian shipments in 1941 reached 25,740 metric tons, the highest since 1929 and 32 percent greater than in 1940. Other data available for 1941 indicate a 17-percent rise in United States production to a record output and a jump in Argentine shipments from 1,220 metric tons in 1940 to 2,981 tons in 1941, or 144 percent.

Feldspar produced in Sweden, Norway, and Finland in normal times is exported largely to the United Kingdom, Germany, and other European countries. Production of feldspar, though generally small, is reported from other widely scattered regions, including Brazil, British India, and Australia.

World production of feldspar from 1937 to 1941, insofar as figures are available, is shown in the following table.

World production of feldspar, 1937–41, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1937	1938	1939	1940	1941
Argentina (shipments)	1,346	620	1,051	1,220	2,981
Australia:					
New South Wales [2]	162	178	(3)	(3)	(3)
South Australia [2]	669	502	615	1,072	(3)
Western Australia (exports)	3,031	2,919	3,853	3,561	(3)
Brazil	8,400	(3)	(3)	(3)	(3)
Canada (shipments)	19,365	12,753	11,306	19,464	25,740
Egypt	158	199	74	138	(3)
Finland (exports)	3,232	5,046	5,596	(3)	(3)
France	8,900	(3)	(3)	(3)	(3)
Germany: Bavaria	9,986	10,419	(3)	(3)	(3)
India, British	495	702	501	(3)	(3)
Italy	13,437	13,391	(3)	(3)	(3)
Norway (exports)	32,555	21,761	21,282	(3)	(3)
Rumania	2,587	1,690	(3)	(3)	(3)
Sweden	49,140	45,111	40,792	(3)	(3)
United States (sold or used)	272,842	199,267	257,534	295,430	344,299

[1] In addition to countries listed, feldspar is produced in China (Manchuria) and Czechoslovakia. Official figures of Czechoslovak output are not available, but it is estimated that the annual production is approximately 30,000 metric tons (Stat. Comm. Czechoslovak Ceram. Soc.).
[2] Includes some china stone.
[3] Data not available.

ASBESTOS

By Oliver Bowles and A. C. Petron

SUMMARY OUTLINE

Sales of domestic asbestos, which reached 24,391 short tons in 1941, were the highest in the history of the industry, exceeding those of 1940 by 22 percent. Their value was 8 percent greater than in 1940. Most of the United States production is of the shorter grades of chrysotile, but long-fiber chrysotile obtained in Arizona is attaining increasing importance. During recent years domestic production has supplied only 4 to 8 percent of national requirements, the rest being imported. The ratio of imports to production was approximately the same in 1941 as in recent years.

As for many years, Canada supplied most of the United States imports. Canadian chrysotile is of superior quality and is a satisfactory raw material for most asbestos products. African chrysotile, of which considerable quantities have been imported during recent years, is interchangeable with Canadian asbestos for many uses, and continuation of such imports is highly desirable to supplement the supply of Canadian long fiber, which may be inadequate to meet growing military requirements.

Chrysotile obtained in Rhodesia and, to some extent, in other African localities is very low in iron and therefore is preferred for the manufacture of electrical tapes and other equipment designed for high electrical resistance. Canadian chrysotile contains considerable magnetic iron oxide (magnetite, Fe_3O_4); in consequence, it is less suitable for the more exacting uses than the African fiber. Furthermore, certain varieties of asbestos, such as amosite and crocidolite (blue), which are obtainable in quantity only in Africa, are adapted to specialized uses for which Canadian fibers are less suitable. For instance, amosite can be made into insulation mattresses of exceptionally low weight per cubic foot and hence is well-qualified for use on naval vessels; and blue asbestos is so resistant to chemical action and so strong that it is preferred for acid filters, and as a constituent of asbestos-cement pressure pipe. As these uses are related intimately to the military program, problems of African supplies and possible utilization of asbestos from alternate sources are subjects of constant and careful study.

The Bureau of Mines has made a detailed investigation of essential requirements for the various grades of asbestos fiber and has explored the possibilities of using substitutes for the more critical grades. The problem of substitution involves replacement wherever possible of critical grades with fibers that are abundant and easily accessible, as well as the use of synthetic fibers in place of asbestos. It has been established that the demand for low-iron chrysotile can be met to some extent by the use of fiber-glass products.

The Bureau of Mines and the Geological Survey made a brief field study of the Arizona asbestos area to determine the facilities afforded by that territory for producing asbestos having qualities that would permit its substitution for special grades of low-iron African chrysotile. A confidential report for use of the War Production Board, covering the major problems of asbestos in its relation to the military program, was prepared by the Bureau of Mines under the auspices of the National Research Council.

To supply defense agencies with current data on the asbestos situation, the Bureau of Mines has, since May 1941, conducted a monthly canvass covering consumption and stocks of all important asbestos-products manufacturers. Although consumption increased progressively throughout the year owing to accelerated demands for military equipment, stocks have increased even more. Unless some unforeseen circumstance should arise to paralyze shipping from Africa, no serious difficulty in providing necessary supplies of essential grades is anticipated.

The accompanying table of salient statistics compares 1941 data with those of 1940. Apparent consumption of raw asbestos (sales plus imports minus exports) reached the highest point in 1941 in the history of the industry.

Salient statistics of the asbestos industry in the United States, 1940–41

	1940		1941	
	Short tons	Value	Short tons	Value
Domestic asbestos—				
Produced:

DOMESTIC INDUSTRY

REVIEW BY STATES

Arizona.—According to reports received by the Bureau of Mines, the production of asbestos in Arizona in 1941 (all from Gila County) was more than twice as great as that in 1940. Sales, also much larger than in 1940, were made by the following companies: Arizona Chrysotile Asbestos Co., Bear Canyon Asbestos Co., Arthur Enders, Roger Q. Kyle, Neighbors & Spencer, Ltd., and Guy Phillips, all of Globe, Ariz.; Fibre & Metal Products, Inc. (formerly Emsco Asbestos Co.), Downey, Calif.; Gladding, McBean Co., 2901 Los Feliz Blvd., Los Angeles, Calif. (formerly owned by Arizona Asbestos Co.); and Johns-Manville Products Corporation, 22 E. 40th St., New York, N. Y. In addition to the firms mentioned, a few small producers made sales to the larger operators.

The Johns-Manville Products Corporation is constructing a new mill at Chrysotile, Ariz., designed in accordance with the results of tests made for several years at Manville, N. J., to determine the best type of equipment for milling Arizona rock and grading the fiber recovered. The output of this mill will add substantially to the supply of Arizona chrysotile, which, because of its low iron content, is especially valuable for certain military manufacturing needs, particularly electrical insulation.

California.—R. B. McIllroy, Lone Pine, produced a small quantity of amphibole asbestos in Inyo County. Kohler & Chase, 26 O'Farrell St., San Francisco, is developing a short-fiber chrysotile asbestos deposit near Monticello, Napa County, about 18 miles north of Napa. Quarry equipment was procured, and a mill was under construction in 1941. A small quantity of fiber has already been produced and sold.

Georgia.—Amphibole asbestos was produced by Philip S. Hoyt near Clayton and by the Powhatan Mining Co. (Woodlawn, Baltimore, Md.) near Dillard, both in Rabun County.

Maryland.—The Todd mine near Pylesville, Harford County, which has for many years produced tremolite asbestos well-suited for making chemical filters, is virtually exhausted.

North Carolina.—Production and sales of amphibole asbestos in North Carolina were over three times as large in 1941 as in 1940. Philip S. Hoyt (Franklin), W. T. Hippey (Micaville), and the Pow-

hatan Mining Co. (Woodlawn, Baltimore, Md.) operated mines in the Micaville-Burnsville area, Yancey County.

Oregon.—Mrs. Flora Winsenberg, Azalea, produced a small tonnage of amphibole asbestos near Rogue River, Jackson County.

Vermont.—Vermont Asbestos Mines Division of the Ruberoid Co., 500 Fifth Avenue, New York City, is the largest producer of asbestos in the United States. An extensive deposit of slip-fiber chrysotile near Eden, Lamoille County, is excavated by open-pit methods, and the rock is milled in a large, well-equipped establishment. Shingle fiber, special brake-lining fibers, and shorter grades were produced in larger quantities in 1941 than in 1940.

LOCATION OF DEPOSITS

The accompanying map (fig. 1) shows the location of chrysotile and amphibole asbestos mines and prospects in the United States. The prospects recorded are confined to those that appear to have commercial importance. More or less promising specimens have been found in many other localities.

The eastern deposits follow closely the highly metamorphosed areas of the Appalachian Mountains. Alteration of ultrabasic rocks (chiefly dunites) resulted—in Vermont and farther north in Quebec, Canada—in the development of chrysotile asbestos, whereas in the southern belt, extending from Pennsylvania to Georgia, the asbestos formed was of the amphibole type, associated with talc, soapstone, greenstone, and other secondary rocks and minerals. Chrysotile is rarely found in the Southeastern States.

The Arizona chrysotile differs entirely in origin from that found in Vermont and Canada. It occurs in bedded veins associated with siliceous dolomites metamorphosed by diabase intrusions. Other western deposits occur generally in highly altered zones of the Rocky Mountain and Coast Ranges.

TRENDS IN CONSUMPTION

The following table shows trends in the asbestos-products industries in the United States during recent years.

Raw asbestos consumed in the United States and asbestos products manufactured in and exported from the United States, 1936–41

Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—Manufactured [1]	Asbestos products—Exported [2]	Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—Manufactured [1]	Asbestos products—Exported [2]
1936	250,922	(1)	$2,479,273	1939	255,547	$97,944,735	$3,354,920
1937	316,263	$96,347,570	3,047,078	1940	262,199	(1)	3,473,248
1938	187,150	(1)	2,533,916	1941	438,991	(3)	4,832,948

[1] Figures of Bureau of the Census (collected biennially for odd years) include value of certain gaskets, packing, and similar products in which little asbestos was employed.
[2] Compiled from records of the Department of Commerce.
[3] Data not yet available

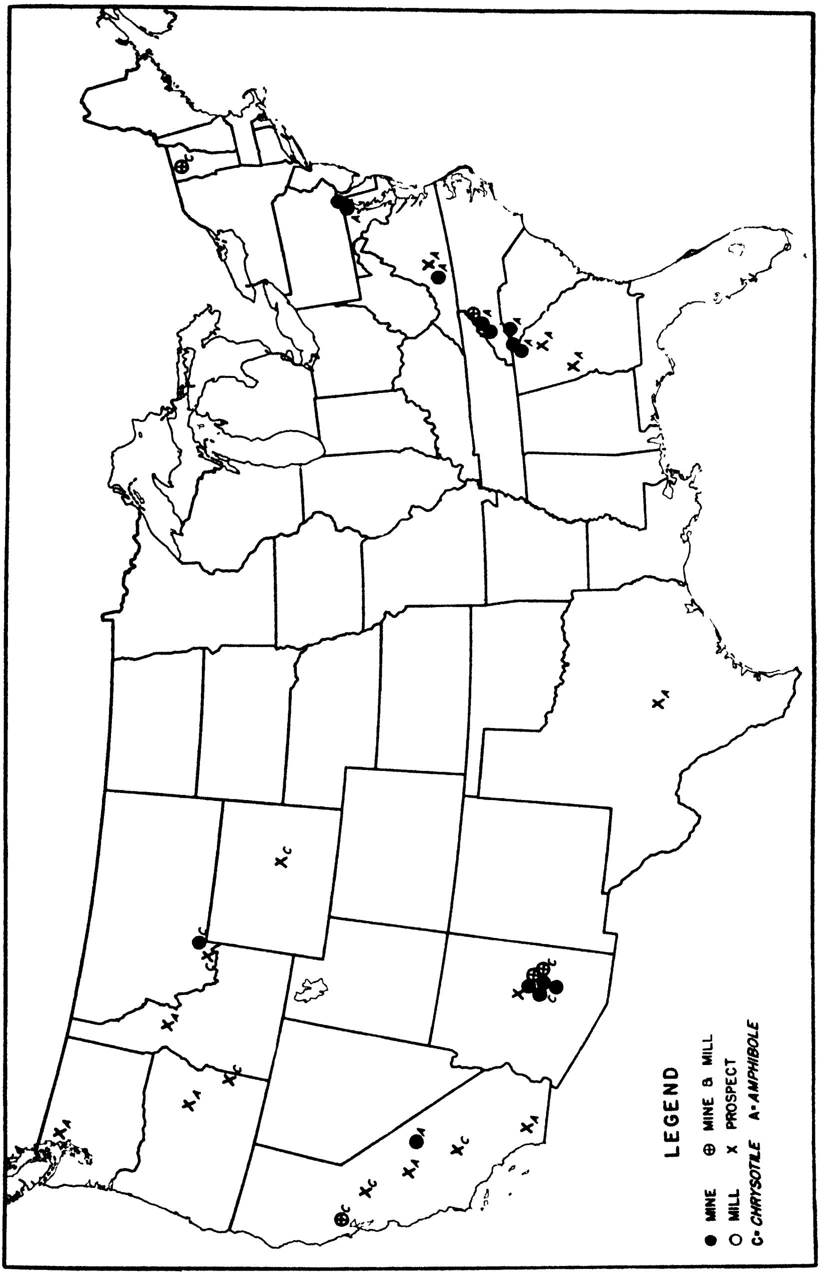

FIGURE 1.—Location of asbestos mines, mills, and prospects in the United States.

The consumption of asbestos is governed to quite an extent by the number of automobiles manufactured because all kinds of automotive transport equipment require brake bands and clutch facings. Activity in building construction also has a decided influence on asbestos sales because asbestos heat-insulation and fireproofing materials, as well as asbestos-cement products (such as shingles, siding, and wallboard), are used extensively. Consumption of asbestos bears a definite relation also to the manufacture of steam engines and similar machinery, because it is used extensively for packings and gaskets, and also for heat insulation in the form of boiler lagging and pipe covering. Figure 2 shows the relationship of asbestos consumption to building construction and the output of automobiles for a period of years.

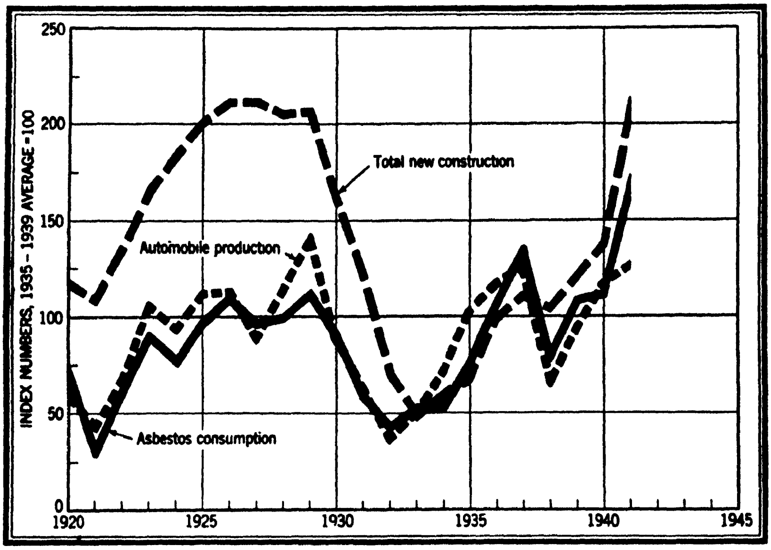

FIGURE 2.—Consumption of asbestos compared with automobile production and construction activity in the United States, 1920–41. Units are reduced to percentages of the 1935–39 average. Statistics on automobiles are from the Bureau of the Census and value of construction from the Bureau of Foreign and Domestic Commerce.

MARKET CONDITIONS

The demand for asbestos attained unparalleled proportions during 1941. The program of national defense created increasing markets for building materials, heat-insulation products, packings, gaskets, and numerous other commodities in which asbestos is an important constituent. The interruption in automobile manufacture was not felt until after the close of the year.

PRICES

Prices for asbestos are quoted upon a short-ton basis from Metal and Mineral Markets, published by the McGraw-Hill Publishing Co., Inc., New York City. Canadian prices are f. o. b. Quebec mines, tax and bags included; Rhodesian, South African, and Russian prices, c. i. f. New York; and Vermont prices, f. o. b. mines, Vermont.

After small advances in shingle, paper, and cement stock during the early months, prices of Canadian fibers were constant from June until the end of 1941, as follows: Crude No. 1, \$700–\$750; Crude No. 2 and sundry crudes, \$150–\$350; spinning fibers, magnesia, and compressed sheet fibers, \$110–\$200; shingle stock, \$57–\$85; paper stock, \$40–\$49; cement stock, \$22–\$30; floats, \$19–\$21; and shorts, \$13–\$17.50. Canadian prices are in United States dollars.

During 1941 African and Russian fibers were quoted only in February, as follows: Rhodesian: Crude No. 1, \$300; Crude No. 2, \$260. South African: Amosite: Grade B 1 (white), \$150; Grade B 3 (dark), \$120; Transvaal Blue: Grade B (long fiber), \$400; Grade S (short fiber), \$150.

Russian quotations were unchanged from 1940 but were purely nominal because no imports of Russian fiber were reported for 1941.

Prices of Vermont shingle and paper stocks were advanced from the 1940 levels in June and other grades in July. Quotations from July to the end of the year 1941 were as follows: Shingle stock, \$57–\$60; paper stock, \$40–\$48; waste, \$30; shorts, \$13–\$26; and floats, \$18.

NEW DEVELOPMENTS

An asbestos deposit that may attain importance is situated 6 kilometers west of Tinaquillo, State of Cojedes, Venezuela. Compania Anonima Minas de Amianto de Tinaquillo, with office in Caracas, has prospected a considerable area by core drilling, and a mill was under construction late in 1941. The fiber is of the chrysotile variety, similar to that in Quebec, Canada. An output of about 6,000 tons of asbestos a year, chiefly of shingle-stock grade, is forecast.

Asbestos-products plants operate in Argentina, Brazil, and Chile. Brazil has deposits of both chrysotile and amphibole. Small exports are reported from Bolivia.

A unique block-caving method has been adopted in several of the large Quebec asbestos mines, with satisfactory results. It is especially advantageous at this time when the industry is operating virtually at capacity to supply British and United States war needs, because underground methods permit almost uninterrupted winter operation whereas activity in open-pit mines is seriously handicapped by the severity of winter weather.

FOREIGN TRADE [1]

The following table shows imports of unmanufactured asbestos into the United States in 1940 and 1941. Total imports in 1941 were considerably larger, both in tonnage and value, than in any previous year. Imports from Africa were at a considerably greater rate than in 1940, a circumstance regarded as highly favorable because much of the African fiber consists of critical grades unobtainable elsewhere.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Asbestos (unmanufactured) imported for consumption in the United States, 1940–41, by countries and classes

[1] In addition to countries listed, asbestos is produced in Bulgaria, Czechoslovakia, and Madagascar.
[2] Data not available.
[3] Exports.
[4] Exclusive of sand, gravel, and stone (waste rock only), production of which is reported as follows: 1937, 3,611 tons; 1938, 2,975 tons; 1939, 3,535 tons, 1940 and 1941, data not available.
[5] Includes asbestos flour.
[6] January to May, inclusive.
[7] January to June, inclusive.

CANADA

Owing to war conditions, no figures for production of asbestos in Canada during 1941 have been released. Production has probably exceeded by a wide margin all previous records because the greatly expanded asbestos-products industries of the United States have depended chiefly on Canada for supplies of raw materials, and England likewise has drawn large supplies from the Canadian mines. Both open pits and underground mines are worked. During much of the year, the mines were operated 24 hours a day on three shifts, and some of them were on a 7-day-week schedule. The asbestos mills were running virtually at maximum capacity. All grades of asbestos were in demand because sales of all types of asbestos products were heavy Sometimes Canadian producers are overstocked with certain grades that move slowly in the market, but during 1941 the demand was distributed so uniformly over the whole range of products that stocks were low in all categories.

Although no figures are available for 1941, the following table is repeated to show conditions as of 1939 and 1940.

Sales of asbestos in Canada, 1939–40, by grades

Grade	1939			1940		
	Short tons	Value		Short tons	Value	
		Total	Average per ton		Total	Average per ton
Crudes	3,121	$938,718	$300.68	2,076	(1)	(1)

Shorts	167,359	2,870,955	17.15	161,615	(1)	(1)
	364,472	15,859,212	43.51	345,581	$15,620,000	$45.20

[1] Data not available.

AFRICA

Southern Rhodesia.—The largest asbestos mine in Rhodesia is the Shabani, which has been a prolific producer for many years. Its output of chrysotile is supplemented by that of the Birthday, Nil Desperandum, Pangani, and Croft mines. No figures are available for production in 1941, but it was probably larger than in 1940. The following table shows production during recent years.

Asbestos produced in Southern Rhodesia, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	57,014	£840,025	1940 [1]	24,391	£474,617
1938	58,811	1,020,921	1941	(2)	(2)
1939	58,313	1,088,782			

[1] January to May, inclusive.
[2] Data not available.

Union of South Africa.—The Union of South Africa is unique among asbestos producers because it furnishes four varieties of fiber—chrysotile, amosite, crocidolite (blue), and anthophyllite. The last variety is used locally, but the other types have a world-wide market.

Amosite and blue are in such active demand for military needs that the schedule of production of these varieties was expanded during the last 6 months of 1941 and will be enlarged further during 1942.

The following table shows production during recent years, but statistics for 1941 are available for the first 6 months only. Figures for the corresponding period in 1940 are: Transvaal 10,371 and Cape Province 3,095 short tons; total value £234,232.

Asbestos produced in the Union of South Africa, 1937–41, by sources

Year	Short tons				Total value [1]
	Transvaal	Cape Province	Natal	Total	
1937	23,921	4,712	(2)	[2] 28,633	£431,212
1938	16,505	6,484	[2] 187	[2] 23,176	416,401
1939	15,827	6,144	79	22,050	517,535
1940	21,011	6,381	(3)	[3] 27,392	492,125
1941 [4]	10,444	3,172	(3)	[3] 13,616	213,430

[1] Value of local sales plus value of exports.
[2] Small production in Natal in December 1936 and in 1937 included in 1938 figures.
[3] Data for Natal not available.
[4] January to June, inclusive.

The following table shows the tonnage of each variety produced from 1937 to 1940 and in the first 6 months of 1941. Figures for the corresponding 6 months of 1940 are as follows: Amosite (Transvaal) 8,368 short tons; chrysotile (Transvaal) 209; blue (Transvaal) 1,730; blue (Cape) 3,095; and anthophyllite (Transvaal) 64.

Asbestos produced in the Union of South Africa, 1937–41, by varieties and sources, in short tons

Variety and source	1937 [1]	1938 [1]	1939 [2]	1940 [2]	1941 [3]
Amosite (Transvaal)	6,531	8,793	11,299	17,767	9,210
Chrysotile (Transvaal)	16,855	[4] 5,573	[4] 612	646	698

[1] Data from Union of South Africa, Department of Mines, Monthly Reports.
[2] Data from Union of South Africa, Department of Mines, Quarterly Reports.
[3] January to June, inclusive.
[4] Includes 187 tons in 1938 and 79 tons in 1939 produced in Natal.

Swaziland.—The Havelock mine in Swaziland near the Transvaal border has become one of the great asbestos mines of the world. Turner & Newall, Ltd., owner of the property, evidently has unbounded confidence in the future of this important chrysotile area because the claims alone cost the company £240,000, and thereafter an additional heavy investment in equipment and development was required before any return was possible. A difficult transportation problem was overcome by means of a 12.6-mile aerial ropeway, with a capacity of 7.5 tons of fiber an hour. Supplies and equipment constitute return loads. It is fortunate that the Havelock mine could attain the status of a major producer at this time and thus offset the great reduction in output of chrysotile in the Transvaal due to depletion of

the once famous Amianthus mine. Production in 1940 was at a rate exceeding 18,000 tons per year, and 1941 production probably was much higher.

CYPRUS

Cyprus normally produces several thousand tons of short-fiber chrysotile a year, and virtually the entire output is exported. However, the island found it rather difficult to carry on foreign trade during 1940 and 1941, and its asbestos-producing activities probably have been curtailed. Exports during recent years are indicated in the following table, but no data are available on production or shipments in 1941.

Asbestos exported from Cyprus, 1937–41

Year	Long tons	Value	Year	Long tons	Value
1937	11,704	£126,371	1940	9,500	(1)
1938	5,578	88,290	1941	(1)	(1)
1939	9,813	(1)			

[1] Data not available.

U. S. S. R.

Large quantities of chrysotile asbestos, similar to that obtained in Canada, are produced in the Bajenova district in the Ural Mountains. A production of 125,000 metric tons was reported for 1937 and of 86,000 tons for 1938, but no data on either production or exports are available for later years. An important asbestos-products-manufacturing industry was established in the country a few years ago, and the factories consume an increasingly large proportion of the asbestos output. Before the war most of the exports were consigned to Germany.

BARITE, WITHERITE, AND BARIUM CHEMICALS

By Bertrand L. Johnson and K. G. Warner [1]

SUMMARY OUTLINE

SUMMARY

New all-time peaks characterized many phases of the domestic barite industry in 1941. All-time highs were reached in the mined production of crude barite (483,391 short tons), an increase of 24 percent over 1940; in the domestic crude barite sold or used by the producers (503,156 tons), an increase of 23 percent; and in the reported consumption of domestic and imported crude barite (490,833 tons), an increase of 21 percent. A new record was also set for the total value of domestic crude barite sold or used by producers in 1941 ($3,134,234), at an average value of $6.23, a little less than that in 1940 ($6.34). Increased demands for crude barite came from the ground (and crushed) barite and barium chemical industries. Imports of crude barite for the 9 months for which data can be published came entirely from Cuba and were far less than for the whole year 1940; the average value also dropped—from $5.59 in 1940 to $5.27 in 1941. Imports of witherite for 9 months were 2,470 short tons; imports for the entire year 1940 were 3,584 tons.

Total sales of barium chemicals were higher both in quantity and value than in recent years. The quantities of lithopone, blanc fixe, artificial barium carbonate, and "other barium chemicals" sold or used by producers in 1941 were all greater than in 1940.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Salient statistics of the barite, witherite, and barium chemical industries in the United States, 1937-41

	1937	1938	1939	1940	1941

Value	$231,622	$153,567	$392,798	$1,112,362	[2] $1,454,520

[1] F. o. b. mine shipping point.
[2] Figures cover January to September, inclusive.
[3] Declared value f. o. b. foreign market.
[4] Barite sold or used by producers plus imports.
[5] Figures not available for publication.
[6] To avoid duplication, the barium chemicals reported here do not include the output of firms that make these chemicals from such products as barium chemicals and imported barite and witherite purchased in the open market.

BARITE

CRUDE

Production.—The same 10 States produced barite in 1941 as in 1940—Arkansas, California, Colorado, Georgia, Missouri, Nevada, South Carolina, Tennessee, Texas, and Virginia. Mine production in 1941 totaled 483,391 short tons, a 24-percent increase over the 390,462 tons mined in 1940. The location of barite mines and barium products plants in the United States is shown on the accompanying map (fig. 1).

Sales.[2]—A new peak was reached in 1941 (see fig. 2) in the quantity of crude barite sold or used by producers in the United States—503,156 short tons. The total value ($3,134,234) was much higher than in any previous year, and there was an increase of 23 percent in quantity and 21 percent in value over 1940. Missouri continued to lead in sales of crude barite, with sales twice as great as those of the next largest producing State and considerably greater than in 1940.

[2] *See also* Johnson, Bertrand L., Marketing of Barite: Bureau of Mines Inf. Circ. 7149, 1941, 16 pp.

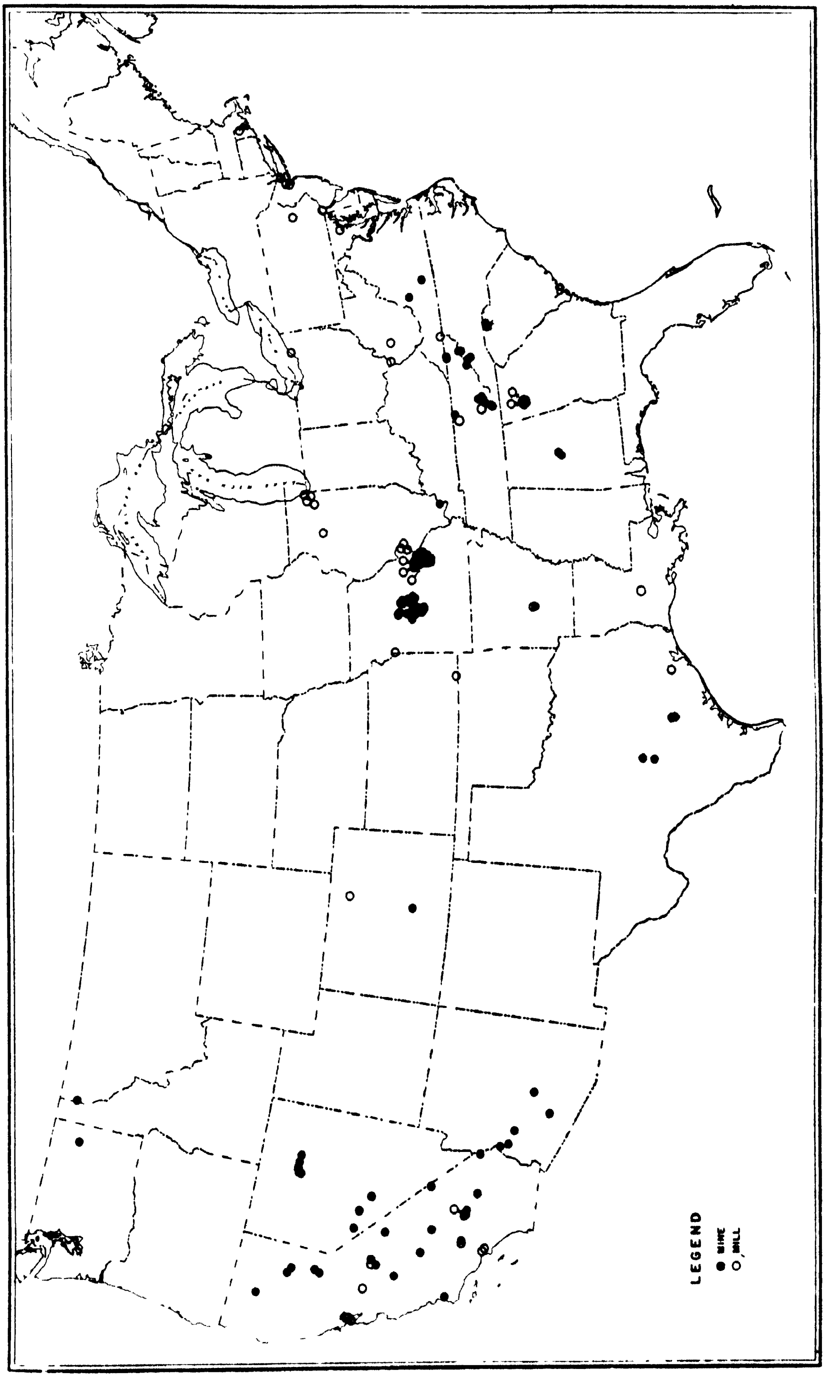

FIGURE 1.—Location of barite mines and barium products plants in the United States.

Tennessee and Georgia were close competitors for second place, Tennessee being apparently slightly in the lead. Both States had large increases over 1940.

Crude barite sold or used by producers in the United States, 1940–41, by States

State	1940		1941	
	Short tons	Value	Short tons	Value
Georgia	92,302	$464,590	104,446	$553,445
Missouri	179,455	1,216,069	212,718	1,337,756
Tennessee	70,767	503,204	104,511	779,565
Other States [1]	66,829	412,880	81,481	463,468
	409,353	2,596,743	503,156	3,134,234

[1] Arkansas, California, Colorado, Nevada, South Carolina, Texas, and Virginia.

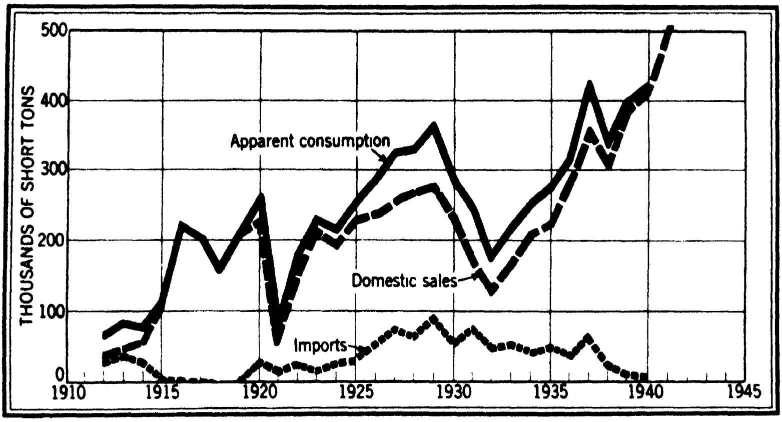

FIGURE 2.—Trends in domestic sales, imports, and apparent consumption of crude barite, 1912–41.

Prices.—The market quotation for crude barite from Georgia, f. o. b. mines, after remaining unchanged at $7 a long ton from 1935 to 1940, increased to $8 a ton in March 1941 and to $9 a ton in April 1942, according to the Engineering and Mining Journal Metal and Mineral Markets.

The price of Missouri crude barite (95 percent $BaSO_4$, less than 1 percent iron) was quoted at $6.25 to $7.00 a short ton throughout 1941, the same as in the later months of 1940, but in April 1942 the quotations rose to $7 to $7.50 a ton. The 93-percent-grade quotations opened in 1941 at $6 to $6.50 a short ton but were lowered slightly to $6 to $6.35 in March 1941 and then in April 1942 were raised to $6.75 to $7.25 a ton.

The average value, f. o. b. mine shipping point, of crude barite for the entire United States declined slightly from $6.34 in 1940 to $6.23 in 1941.

Consumption.—The following tables show the consumption of crude barite by uses and by States.

Crude barite (domestic and imported) used in the manufacture of ground barite and barium chemicals in the United States, 1937–41, in short tons

Year	In manufacture of— Ground barite	Lithopone	Barium chemicals	Total
1937	148,930	162,681	72,371	383,982
1938	[1] 193,728	117,007	54,250	364,985
1939	[1] 192,112	141,556	58,015	391,683
1940	[1] 200,899	136,885	66,604	404,388
1941	[1] 243,846	153,982	93,005	490,833

[1] Includes some crushed barite.

Crude barite (domestic and imported) used in the manufacture of ground barite and barium chemicals in the United States in 1941, by States

State	Product manufactured	Plants [1]	Barite used (short tons) [2]

Texas	do	1	
		35	490,833

[1] A plant producing more than 1 product is counted but once in arriving at State totals.
[2] Includes some crushed barite.

Deposits and technologic developments.—Several articles descriptive of barite deposits and technology, other than those referred to in other parts of this chapter, have appeared in recent months.[3]

Foreign trade.—All of the crude barite imported into the United States in the first 9 months of 1941 came from Cuba. The rate of importation, however, was far less than in 1940, and only 168 tons valued at $886 came into this country from January to September 1941, compared with 7,391 tons valued at $41,342 in the whole year 1940. The average value of the barite imported declined slightly—from $5.59 in 1940 to $5.27 in the first 9 months of 1941. Exports of crude barite from the United States are not separately recorded in the foreign trade statistics.

World production.—Barite production throughout the world, insofar as figures are available, is shown in the accompanying table.

Canadian production of barite was small until mining operations were begun in 1941 at the deposit discovered the preceding year at

Pembroke, Nova Scotia. Production in Canada during 1940 was only 307 metric tons, whereas in 1941, largely because of the above-mentioned operations, it rose to 6,043 metric tons. Most of this came from the Nova Scotia deposit, but a few hundred tons were shipped from a deposit near Golden, British Columbia, most of it to a grinding plant in Montreal and the remainder to oil wells in Turner Valley.[4]

The Pembroke barite deposit in Nova Scotia is owned by the Springer Sturgeon Gold Mines, Ltd., and operated by its subsidiary, Canadian Industrial Minerals, Ltd. Two recent papers by Cameron[5] and Campbell[6] describe the deposit, the barite, the mine and mill operations, and possible markets. The barite is hard and massive and is gray to dark red, replacing iron-bearing calcareous sediments.

World production of barite, 1937–41, by countries, in metric tons[1]

[1] In addition to the countries listed, barite is produced in China, Czechoslovakia, Japan, Spain, and U. S. S. R., but data on production are not available.
[2] Data not available.
[3] Official figures which, it is reported, cover only output of mines included under the mining law.
[4] Figures cover January to June, inclusive.

Quarrying operations, and the construction of a 100-ton mill at tidewater at Walton on the Midas Basin arm of the Bay of Fundy, were commenced in February 1941. The mill was put in operation late in May 1941. Ore containing admixed impurities is treated at a washing plant adjacent to the quarry to remove the impurities before it is trucked to the mill over an all-weather road. The first shipment of the ground barite (96.85 percent $BaSO_4$) was made to Trinidad in June 1941. Several other shipments have since been made to Trinidad and one small shipment to Peru. In addition, about 100 tons of ground

[5] Cameron, A. E., Barytes Deposit at Pembroke, Hants County, Nova Scotia: Proc. Nova Scotia Inst. Science, Halifax, Nova Scotia, vol. 20, part 3, 1940–41, 1941, pp. 57–63.
[6] Campbell, C. O., Barytes at Pembroke, Hants County, Nova Scotia: Canadian Inst. Min. and Met. Bull. 362, June 1942, pp. 299–310.

barite were marketed in Ontario as a filler in rubber, paints, and varnishes, and a carload of crude ore was shipped to Montreal to determine its suitability for use in the manufacture of various barium compounds. Campbell pointed out that the Canadian market for barite and barium products is small, and to take care of any substantial domestic production it would be necessary to develop export markets; the most promising outlet appears to be in its application as a weighting material in oil-well drilling, in which the color of the barite is said to be of little or no importance. However, leaching of this ore with a 10-percent acid solution is said to remove the iron and to yield a white product.

In 1940 a barite-grinding plant was built at Regla near Habana, Cuba; according to report, most of the Cuban production is shipped to this plant, and in consequence shipments to the United States have dropped. Barite production in Cuba in 1940 is reported to have been 16,105 metric tons compared with 12,000 tons in 1939. Figures for 1941 are not available. Much of the ground barite from the Regla plant is shipped to Trinidad for use in oil-well drilling.

GROUND (AND CRUSHED)

Sales.—The quantity of ground (and crushed) barite sold or used by producers in the United States in 1941 was much larger than the previous all-time high of 1940—234,877 short tons in 1941 compared with 184,390 tons in 1940—and the total sales value likewise showed a marked increase over 1940, rising to $4,606,832. The number of plants producing ground or crushed barite remained at 16, as in 1940 (see accompanying table). By far the predominant use of this material continued to be in well drilling.

Ground (and crushed) barite sold or used by producers in the United States, 1937–41

	1937	1938	1939	1940	1941
Plants	12	14	13	16	16
Short tons	129,777	161,422	170,695	184,390	234,877
Value	$2,249,612	$2,786,823	$2,902,973	$3,697,806	$4,606,832

Ground (and crushed) barite sold or used by producers, 1939–41, by consuming industries

Industry	1939		1940		1941	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Well drilling	125,560	74	138,055	75	154,760	66
Paint	9,750	6	11,056	6	31,009	13
Glass	12,586	7	12,697	7	22,615	10

Undistributed	19,480	11	18,299	10	16,693	7
	170,695	100	184,390	100	234,877	100

Prices.—Prices quoted from Chemical Industries, New York, for ground barite, carlots, 350-pound barrels, works, ranged from $25.15 to $27.65 a short ton for 1941 compared with $25.15 for 1940.

Foreign trade.—Considerable ground barite is exported from the

United States, but the data regarding these exports are not separately recorded. A few thousand tons are usually imported annually; but in 1940 only 314 short tons were entered, and in the first 9 months of 1941 there were no imports of ground barite.

Ground barite imported for consumption in the United States, 1937–41

[Value at port of shipment]

1939	1,590	14,999			

WITHERITE

Deposits in North America.—Witherite deposits have been reported in both Canada and the United States, but the only occurrence of present commercial importance is in the latter country. In Canada two occurrences of witherite are known, neither of which is believed to have economic importance. The first is in the old Porcupine mine in the Rabbit Mountain area of the Thunder Bay district of Ontario, about 20 miles west-southwest of Port Arthur on Lake Ontario. The witherite here occurs [7] in a composite vein 1 to 4 feet thick in a fault cutting gently dipping pre-Cambrian black slates and associated diabases. The vein filling consists chiefly of calcite, quartz, fluorite, witherite, galena, sphalerite, pyrite, argentite, and native silver, as well as some chalcopyrite and pyrrhotite. Witherite lenses up to 3 inches thick and 2 feet long have been reported. The other Canadian occurrence is in the recently developed barite deposit at Pembroke, Hants County, Nova Scotia, where Campbell [8] states that a small amount of barium is invariably present in the ore as witherite, and that some samples have shown as high as 1.5 percent witherite. The barite deposit apparently resulted from replacement of a limestone conglomerate of Upper Mississippian age along a zone of brecciation.

In the United States, witherite deposits occur in Alaska, Arizona, California, Kentucky, Montana, Nevada, New Mexico, and Tennessee. The deposits in Kentucky, Nevada, and Tennessee appear to be small and of mineralogic interest only. In Kentucky crystals of witherite have been found in some of the fluorspar-galena veins in the central part of the State.[9] In Nevada only occasional small crystals of witherite have been found. These were in barite veins

near Argenta, Lander County.[10] In Tennessee a small quantity of witherite is reported as a surface alteration product in a barite vein in Rutherford County.[11] No details are available regarding the New Mexican occurrences reported in Socorro and Dona Ana Counties.[12] The deposits in Alaska, Arizona, and Montana contain considerable witherite, but the extent of each of these deposits is still unknown. According to correspondence from the Alaska Department of Mines dated November 24, 1941, and February 17, 1942, the Alaska deposits, on the shore of Kuiu Island, in southeastern Alaska, consist of a short irregular vein averaging 16 inches thick, scattered small veinlets, and beach pebbles, comprising in all a very small tonnage. In Arizona, witherite forms about 5 percent of the gangue of certain lead veins in the Castle Dome district, Yuma County, according to a letter from F. W. Galbraith of the Arizona Bureau of Mines dated January 20, 1942.[13] The Montana deposits consist of lenses and masses of witherite and irregular lumps up to 2 feet in diameter in solution cavities in Altyn pre-Cambrian limestone just above the plane of the Lewis overthrust fault at Many Glacier in Glacier National Park.[14]

Witherite occurs in California in Mariposa and Shasta Counties. In Mariposa County it is associated with barite in veins cutting sedimentary rocks on the western flank of the Sierra Nevada granite batholith in two localities about 6 miles apart. The northernmost of these, in the Merced River Valley near the El Portal entrance to Yosemite National Park, consists of a group of steeply dipping veins striking north. The veins apparently were formed by replacement of limestone in an isoclinally folded series of Carboniferous sediments by barium-bearing solutions given off by the underlying Jurassic (or Cretaceous) Sierra Nevada granite batholith. This group of veins, reported traceable over a distance of 3 miles, provides a mixture of witherite and barite sold as a flux to glassmakers.[15] This deposit is the only commercial producer of witherite in the United States.

The other locality in Mariposa County is at Devil's Gulch, 6 miles south of El Portal, where a north-striking replacement deposit of barite and witherite in limestone is reported traceable 4,500 feet.[16]

In Shasta County massive witherite is reported on Beegum Creek near Platina.[17]

Production.—The Baroid Sales Division of the National Lead Co., which operates the mine near El Portal, Calif., is the only producer of witherite in the United States. Figures on output are not available for separate publication but are combined with those of barite.

Prices.—The price of ground witherite in 1941, according to Chemical Industries, New York, remained constant at $43.00 a ton in carlots, bags, works, for the 90-percent grade. In 1940 prices had ranged between $43 and $47 a ton.

Foreign trade.—Imports into the United States come entirely from England and range from 2,000 to nearly 5,000 tons a year. Imports for the first 9 months of 1941 totaled 2,470 short tons valued at $56,789. Exports of witherite from the United States, if any, are not separately recorded in the foreign trade statistics.

BARIUM CHEMICALS

Sales.—Both the total quantity and the value of barium chemicals sold or used by producers in 1941 were much larger than in 1940. Greater quantities of lithopone, blanc fixe, artificial barium carbonate, and "other barium chemicals" were sold. Another new high record was made in sales of artificial barium carbonate (chemically precipitated). Increases in value in 1941 over 1940 were recorded for all the barium chemicals listed in the accompanying table.

Lithopone is used principally in the manufacture of paints, enamels, and lacquers, 75 percent of the total sold or used by producers in 1941 going into those products.

Barium chemicals sold or used by producers in the United States, 1937–41 [1]

Chemical	1937	1938	1939	1940	1941

	142,759	100	151,802	100	176,642	100

[1] Does not include cadmium lithopone.

Prices.—Quoted prices for domestic lithopone in 1941 were higher than in 1940, and prices for titanated lithopones likewise rose above the 1940 level. Prices for precipitated barium carbonate in 1941 ranged from $45.00 to $65.00 compared with $45.00 to $62.50 in 1940. There were no changes in barium chloride prices. Barium chlorate prices remained at 45 cents a pound throughout 1941, which was the peak price of 1940. Barium dioxide was quoted at 10 cents a pound throughout 1941 compared with a range of 10 to 12 cents a pound in 1940. There were no changes in barium hydrate prices. Barium nitrate had a wider range of prices in 1941 than in 1940 and rose to a higher price—12½ cents a pound. Blanc fixe quotations showed a marked decrease—$50.00 to $80.00 a ton in 1940 and $35.00 to $46.50 in 1941.

[1] Chemical Industries (formerly Chemical Markets), New York (monthly).
[2] Lowest price for pulp grade, highest for high-grade precipitated.

Foreign trade.—Foreign trade figures for barium chemicals are available for publication only for the first 9 months of 1941. During this period the hydroxide and lithopone were the only barium chemicals imported. Both the quantity imported (247 short tons) and the value ($8,418) of the barium hydroxide were much larger than for the entire 12 months of 1940. Only 112 pounds of lithopone were imported from January to September.

Exports of lithopone in the first three quarters of 1941 were greater than in the entire year 1940, both in quantity and total value, and

had a much larger average value. They were greater than in any year since 1922, when exports of barium products were first recorded separately.

POTASH

By J. H. Hedges

SUMMARY OUTLINE

The often-repeated claim that development of potash resources within the United States in the brief period since the last war had relieved this country from dependence on foreign supplies was confirmed definitely in 1941, when imports dropped to a few thousand tons and were exceeded by exports drawn from domestic sources and shipped to neighboring countries. Receipts of foreign potash declined sharply in 1940, but imports still were substantial and permitted gradual shifting of the load to American producers. In 1941, although one major plant was strike-bound for 3½ months and its output for the year thereby reduced more than 30 percent, production was greater than ever before, and supplies were adequate to meet a 13-percent rise in consumption.

The United States potash industry is virtually a post-war product of the First World War, born of the realization that complete dependence on foreign supplies invited repetition of the serious wartime shortage that skyrocketed prices of muriate to over $500 a ton in 1915–16. In the intervening 25 years, the combined efforts of Government and private agencies have built up an industry that in 1941 produced almost a million tons of marketable salts containing 525,000 tons of K_2O. Plant additions during the year increased further the capacity to produce refined salts, now estimated to total well over a million tons a year, equivalent to more than 600,000 tons of K_2O. The mines in the Carlsbad area are capable of producing in excess of refinery capacity up to 200,000 tons a year of 20- to 25-percent manure salts that can be employed satisfactorily in compounding some fertilizer mixtures.

The virtual cessation of imports and the increased industrial use of chemical grades were the chief war-induced factors affecting the potash industry. Formerly extensively imported, all potash salts used in the manufacture of black powder, in the Houdry process for the manufacture of aviation gasoline, in the glass industry, and in the heat treatment of aluminum alloys had to be supplied by American producers. The manufacture of potassium chlorate, made by electrolysis of a solution of potassium chloride, was resumed in this country in 1939 in anticipation of interruption of imports. Classed as a material essential for national defense, normal consumption has been 5,000 to 7,000 tons a year. Its principal peacetime use is as the active oxidizing

agent in match heads. Other uses are in flares, fusees, and fireworks for military operations. Production from several plants is reported to be at the rate of about 7,200 tons a year.

Potassium chloride pure enough to be acceptable for industrial and chemical use is made by only two plants, one of which suffered a prolonged strike that reduced output materially. By Government order chemical requirements were given priority over fertilizer needs. As a result, supplies at times were short and open-market offerings were limited, although contract deliveries were well-maintained. The tight spot market brought out some resale offerings at premium prices. Except for these speculative flurries, prices were steady throughout the year.

Except for shipments to Canada, exports were sharply reduced. By Presidential proclamation of January 10, 1941, effective February 3, potash salts were placed under export control. Thereafter export licenses were required for all shipments abroad. Cessation of shipments to Japan, formerly the largest importer of American potash, more than offset increases in other directions and resulted in a sharp drop in total exports.

The potash salts sold were largely refined or processed products derived from bedded deposits in New Mexico, brines in California and Utah, and as a byproduct of manufacturing processes in Maryland. A few tons of cotton-boll ashes were sold in Texas for their potash content. In former years crude alunite has been used in a limited way for fertilizer, but no shipments were reported in 1941. The United States Potash Co., Potash Co. of America, and Union Potash & Chemical Co. mined 82 percent of the total output (K_2O) from salt beds; and the American Potash & Chemical Corporation and Bonneville, Ltd., produced 17 percent from brines. U. S. Industrial Chemicals, Inc., and the North American Cement Corporation accounted for the other 1 percent, which was salvaged from waste products.

Uninterrupted operation of the five principal plants during 1942 should provide ample potash for presumptive needs. Continued increase in use of fertilizers in this country is anticipated but may be checked by shortage of ingredients other than potash needed for preparing the customary mixtures. Explosives manufacture and other war uses doubtless will have first call on nitrates, hence some stringency in supplies for use in fertilizers is not unlikely. Reserves of Chilean nitrate are ample, but supplies from that source are subject to the difficulties and hazards of ocean transportation. New nitrogen plants recently or soon to be completed will increase the domestic supply materially. If the war continues to follow the present pattern, in which bombing plays the leading role, there probably will be enough nitrogen for all uses. Bombs impelled by gravity are much more economical in expenditure of explosives than shells propelled from great guns by enormous charges of powder. Greater use of artillery might result in a shortage of nitrogen for fertilizer and a corresponding reduction in the demand for potash. The needs of other nations that look to the United States for their potash are moderate and can easily be supplied. Except for Canada and Cuba, transportation and distribution are likely to present greater difficulties than supply. The industry appears to be in a favorable position to meet any demands likely to be made upon it in 1942.

Salient statistics of the potash industry in the United States, 1940–41

	1940	1941
Production:		
Potassium salts (merchantable) short tons	658,249	986,458
Approximate equivalent, K_2O do	379,679	524,875
Sales by producers:		
Potassium salts do	677,892	994,843
Approximate equivalent, K_2O do	393,058	531,346
Value at plant	$12,562,050	$17,368,237
Average per ton	$18 53	$17.46
Imports:		
Fertilizer materials short tons	274,473	[1] 36,499
Approximate equivalent, K_2O do	115,241	[1] 10,948
Value	$5,148,852	[1] $753,786
Chemical materials short tons	14,564	[1] 10,173
Approximate equivalent, K_2O do	3,449	[1] 2,075
Value	$2,411,919	[1] $3,491,535
Exports		
Fertilizer materials short tons	93,060	[1] 69,092
Approximate equivalent, K_2O do	55,836	[1] 37,900
Value	$3,141,170	[1] $1,991,727
Chemical materials short tons	14,180	[1] 9,497
Approximate equivalent, K_2O do	7,000	[1] 4,700
Value	$3,096,909	[1] $2,040,956

[1] January to September, inclusive.

PRICES

Prices quoted in schedules issued by producers in 1940 for the 1940–41 fertilizer season were unchanged through May 1941. Price lists for the new season—June 1, 1941, to May 31, 1942—continued the old prices and terms, except for an increase of 1½ cents to 55 cents per unit for 50-percent muriate, produced chiefly by dilution of the standard 60-percent product. As long as refining capacity is adequate there seems to be little excuse for the 50-percent grade, and producers have sought to discourage its use. Wartime shortage of rail and ocean transportation facilities furnishes another potent argument for employing the more concentrated material. Base prices were as follows:

Muriate of potash, 60 percent K_2O minimum	53½ cents per unit K_2O.
Muriate of potash, 50 percent K_2O minimum	55 cents per unit K_2O.
Manure salts, run-of-mine grade	60 cents per unit K_2O.
Sulfate of potash, 90/95 percent K_2SO_4—basis 90 percent K_2SO_4	$36.25 per short ton.
Sulfate of potash-magnesia—minimum 40 percent K_2SO_4, 18.50 percent MgO	$26.00 per short ton.

These prices were ex-vessel at customary Atlantic and Gulf ports and were subject to the following discounts:

On orders placed by June 30, 1941, for delivery during June or in substantially equal monthly quantities from July 1, 1941, to January 31, 1942, a discount of 8 percent.

Upon acceptance of delivery of entire tonnage on order by January 31, 1942, an additional allowance of 4 percent.

On orders placed after June 30, 1941, for delivery at buyer's plant before and including May 31, 1942, list prices applied.

Deductions of 11.2 cents a unit and 8 cents a unit from ex-vessel prices for muriate were offered for purchase f. o. b. Carlsbad and Trona, respectively. This provision was operative throughout the calendar year 1941 and appears to have benefited about one-third of the tonnage sold through saving in freight. Around 40 percent of the f. o. b. shipments were manure salts. The split-discount system inaugurated in 1940 functioned successfully to discourage overorder-

ing and subsequent cancelations, long a disturbing factor in the market and a hazard for producers.

Perhaps the most startling price development was a cut early in June in the base price for manure salts from 60 to 21 cents per unit. The supplementary schedule announcing the price reduction stated by way of explanation—

The very serious scarcity of ships and prohibitive charter rates asked when boats are obtainable combine to make it economically unsound and next to impossible to move this low-grade commodity to Atlantic ports via water transportation at the present time. The outlook for the balance of the season is even less hopeful. For these reasons it is found necessary to announce the above stated price change.

Average prices for the various fertilizer salts for each month are shown in the following table.

Ex-vessel port prices of potash salts in the United States in 1941

Period	Muriate of potash in bulk		Sulfate of potash, 90 percent K_2SO_4, per short ton	Sulfate of potash-magnesia, 40 percent K_2SO_4, per short ton	Manure salts, 25 to 30 percent K_2O, per unit
	60 percent K_2O, per unit	50 percent K_2O, per unit			
January to May, inclusive	$0.535	$0.535	$36.25		$0.60
June	.471	.484	31.90	$22.88	.185
July	.471	.55	36.25	26.00	.21
August to December, inclusive	.535	.55	36.25	26.00	.21

CONSUMPTION AND USES

Potash salts containing approximately 500,000 short tons of K_2O moved into channels for consumption in the United States and its possessions in 1941. About 90 percent was for fertilizer and 10 percent for industrial use. Consumption in industry was around 14,000 tons of K_2O more than in 1940, due mainly to expanded manufacture of black powder and aviation gasoline, in which potash salts are employed. Other uses that have increased as a result of the war include the manufacture of glass and the heat treatment of aluminum alloys. The following table, combining information from various sources, indicates that consumption in the United States and its possessions in 1941 was 504,500 short tons of K_2O—an increase of around 15 percent from 1940. The picture is incomplete, as it is not permitted to disclose foreign trade statistics for the final quarter of 1941.

Sales of primary potash in the United States for consumption and export, 1940–41, in short tons of K_2O

	1940	1941 [1]
Deliveries of potash by member companies reported by American Potash Institute—		
In United States and possessions:		
Agricultural	417,943	435,940
Chemical	37,815	51,962
For export	24,046	26,868
	479,804	514,770
Imports plus sales of nonmember producers	21,737	[1] 32,330
	501,541	[1] 547,100
Total exports	[2] 62,836	[1] 42,600
Actual sales for consumption in the United States	[2] 438,705	[1] 504,500

[1] Figures for imports and exports for 1941 cover January to September, inclusive.
[2] Corrected figure.

PRODUCTION AND SALES

The rising production curve turned more sharply upward in 1941 to record an increase of 50 percent over 1940 in marketable potash salts produced by mines and plants in the United States. The average grade was 53.21 percent potash, and the gain in equivalent potash was 38 percent. Sales 47 percent above 1940 closely approached a million tons of salts containing 531,346 short tons of K_2O, equal to 97 percent of total deliveries for consumption and export and exceeding production by 6,471 tons. The prolonged strike at Trona cost some 30,000 to 40,000 tons of potential K_2O production.

The uneconomic demand for 50-percent muriate continued, despite the fact that this impure material costs the consumer more per unit of potash than the 60-percent grade. Fifty-percent muriate is made by mixing the normal product of the refining processes with run-of-mine salts in suitable proportions or by adjusting the process to leave more impurities in the product. If wartime demand should outstrip refinery capacity, this uneconomic practice might be justified as a temporary expedient; otherwise, it seems inexcusable.

Production of the various grades of salts in 1941 was as follows:

	Short tons
Muriate of potash, 60 percent K_2O minimum	663, 608
Muriate of potash, 50 percent K_2O minimum	85, 398
Manure salts, run-of-mine	154, 979
Sulfate of potash and sulfate of potash-magnesia	82, 473
	986,458

GOVERNMENT ACTIVITIES

On recommendation of the Administrator of Export Control and pursuant to the provisions of section 6 of the act of July 2, 1940, entitled "An Act to Expedite the Strengthening of the National Defense," the President on January 10, 1941, issued a proclamation placing copper, brass, bronze, zinc, nickel, and potash under the export-licensing system. The effective date of the proclamation was February 3, 1941.

The Executive order prescribing regulations governing the exportation of materials designated in the proclamation of January 10 stated that potash should be construed to include the following:

Potassium salts and compounds
- Potassium hydroxide (KOH)
- Potassium carbonate (K_2CO_3)
- Potassium chlorate ($KClO_3$)
- Potassium perchlorate ($KClO_4$)
- Potassium cyanide (KCN)
- Potassium iodide (KI)
- Potassium nitrate (KNO_3)
- Potassium permanganate ($KMnO_4$)
- Potassium acetate ($KC_2H_3O_2$)
- Potassium bicarbonate ($KHCO_3$)
- Potassium bitartrate ($KHC_4H_4O_6$)

Potassic fertilizer materials
- Potassium chloride (KCl)
- Potassium sulfate (K_2SO_4)
- All other potassic fertilizer materials containing 27 percent or more potassium oxide (K_2O) equivalent

All combinations and mixtures of any of the foregoing containing potash salts of 27 percent or more potassium oxide (K_2O) equivalent

The Government-sponsored program for expanding aluminum production to meet wartime needs has again focused attention on alunite deposits in several of the Western States. Attempts during the last war to utilize alunite for the production of potash, with alumina as a byproducts, proved noncommercial under normal conditions, and plants have remained idle since 1918. However, experimentation continued, and several processes were developed. The interest now has shifted to aluminum, but for every ton of aluminum produced from alunite the process will yield about a ton of potassium sulfate. Virtually all alunites contain some sodium, replacing the potassium of the pure mineral. Soda and potash are difficult to separate, hence potassium sulfate from alunite would be contaminated with sodium sulfate to some degree. If proposed plants to make 60,000,000 pounds of aluminum a year from alunite are built they will produce around 30,000 tons a year of potassium sulfate. Both Kalunite, Inc., and the Reynolds Metal Co. are seeking Government funds for aluminum plants. Kalunite controls deposits in Utah and Washington, and Reynolds is reported to be investigating a deposit in Arizona.

REVIEW BY STATES

California.—A strike, called March 14, closed the plant of the American Potash & Chemical Corporation at Trona. Operations were not resumed until July 2, when two-thirds of the workers accepted a company offer and returned to work. Some strikers continued to hold out and picketed the plant for another month before voting to return to work. The settlement was reported to provide a wage scale of 78 cents to $1.20 an hour compared with a previous scale of 67½ cents to $1.05. This company—only producer of potash in the State—is likewise an important producer of borax. Supplies of both potash and borax were seriously affected by the shut-down. Other products of the plant are soda ash, salt cake, sodium-lithium phosphate, and bromide, all extracted from the brine of Searles Lake. The original holdings of the company, which has been operating at Trona contin-

uously since 1915 and was the first American producer of potash in important quantity, comprised placer claims located and patented before enactment of the mineral-leasing law in 1922. Present production is largely from areas leased from the Government.

Maryland.—At the Security plant of the North American Cement Corporation near Hagerstown, impure sulfate of potash was recovered from cement-kiln flue dust. At Baltimore, United States Industral Chemicals, Inc., produced mixed sulfate and chloride as a byproduct of the manufacture of industrial alcohols from molasses. During the acute potash shortage that developed during the World War of 1914–18, a number of industrial plants devised methods for recovering potash salts from plant wastes. However, when imports

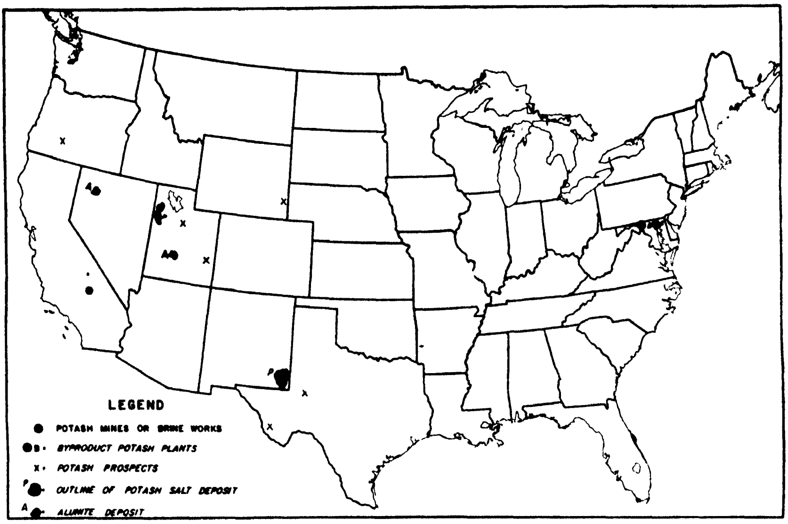

FIGURE 1.—Location of potash mines or brine works, prospects, deposits, and byproduct potash plants in the United States.

were resumed after the war and prices returned to normal, most of these operations became unprofitable and were discontinued. The only exceptions were these two plants in Maryland that each year have contributed several thousand tons to the potash supply.

New Mexico.—The three companies operating in the Carlsbad area mined 2,270,000 tons of ore from rich sylvinite and langbeinite beds at depths ranging from 800 to 1,000 feet. Some run-of-mine ore was shipped to satisfy the demand for manure salts and some was used in mixing to make the 50-percent grade, but the bulk of the raw ore was processed to yield the high-grade salts that constitute a growing percentage of the total output of marketable salts. Production from this field began only 10 years ago with the shipment of a few carloads of manure salts by the United States Potash Co. in 1931, followed a few months later by first shipments from its refinery. The Potash Co. of America was next in the field, beginning to ship manure salts in 1934 and high-grade concentrates in 1935. The growth of these two companies was rapid, and rising output from the district received a further boost with the advent of the Union Potash & Chemical Cor-

poration, which began shipments late in 1940 and completed its first full year of operation in 1941. Although underground conditions are similar at the three properties, operations of the three companies differ markedly in some respects. The refinery of the United States Potash Co. extracts high-purity potassium chloride from sylvinite by solution and fractional crystallization. More recently, a gravity-concentration unit has been added that yields a somewhat lower-grade product. The Potash Co. of America employs a soap flotation process characterized by flotation of the sodium chloride mineral halite and depression of the potassium chloride mineral sylvite. The resulting high-grade product retains the characteristic reddish color of the ore, which is derived from minute impurities. The Union Potash & Chemical Corporation mines both sylvinite (a mixture of sylvite and halite) and langbeinite (K_2SO_4, $2MgSO_4$). The sylvinite is treated by tabling and flotation, using a reagent that floats the sylvite. The langbeinite is washed to remove sodium chloride, centrifuged, and kiln-dried. Some is marketed in this form as sulfate of potash-magnesia, and some is hydrated and used in the manufacture of potassium sulfate by base exchange with potassium chloride. Under carefully controlled conditions, the reaction between the magnesium sulfate of the hydrated langbeinite and potassium chloride brine is rapid and virtually complete. The potassium sulfate produced by this method is high-grade and the byproduct magnesium chloride will be utilized for the production of magnesium metal in a plant soon to be operated by the company near Austin, Tex., where low-cost hydroelectric power is available.

Utah.—Bonneville, Ltd., 540 West Seventh South, Salt Lake City, operating on the salt flats near Wendover in western Utah, doubled the area of its evaporating ponds in preparation for the 1941 season. Earlier difficulties experienced in preventing loss of brine due to leakage from the ponds have been overcome, and improvements in operating the ponds and harvesting the crystallized salts have been introduced. Over 40 miles of collector ditches, fanning out from two pump stations, convey brine to pumps that deliver it to desired points in the ponds. Evaporating ponds extend about 9 miles south from the highway and back on a parallel line to the crytallizing ponds adjacent to the highway. Baffles in the evaporating ponds cause the brine to travel about 30 miles from the point of entry to the crystallizing ponds, where a crystalline mixture of KCl and NaCl is precipitated. The crystallized salts are harvested at the end of the evaporating season and hauled to the mill, where the potash salt is separated by flotation. The muriate produced is about 96 percent KCl. Output in 1941 was nearly double that in 1940 but was less than anticipated because the unusually wet season was unfavorable for this type of operation. Precipitation at Wendover in 1941 was reported to be the heaviest since 1926. The capacity of the present lay-out in a favorable season is believed to be nearly double the quantity produced in 1941. Dry winds, usually prevalent for 6 months or more of the year in this desert region, are the chief agents of rapid evaporation and are more effective than a few extra degrees of temperature. The air immediately above the ponds becomes saturated, and evaporation virtually ceases unless there is enough wind to carry away the vapor.

FOREIGN TRADE [1]

The publication of information regarding exports and imports of all kinds was discontinued October 1. Hence, any data on foreign trade in 1941 contained in this report cover only the 9-month period from January to September.

Imports.—The quantity, average grade, and total declared value of potash salts imported in 1940 and during the first 9 months of 1941, the approximate K_2O equivalent of imports, and the countries from which shipments were made in 1941 are shown in the following tables.

Potash materials imported for consumption in the United States, 1940–41

Material	Approximate equivalent as potash (K_2O) (percent)	1940				1941 (Jan.–Sept.)			
		Short tons	Approximate equivalent as potash (K_2O)		Value	Short tons	Approximate equivalent as potash (K_2O)		Value

[1] Figures for 1940 in Minerals Yearbook, Review of 1940, p. 1351, should read—Muriate: France, 124,995 tons; Belgium, none. Sulfate: Germany, 195 tons; Netherlands, 305. Potash-magnesia sulfate: Germany, 3,885 tons; Netherlands, 15. Caustic: Germany, 5 tons; France, none. "All other": Italy, 22 tons; Japan, 9. Country totals: Belgium, 748 tons, $31,079; France, 186,308 tons, $3,206,431; Germany, 5,711 tons, $144,421, Italy, 1,479 tons, $291,054; Latvia, 9 tons, $1,880; and Netherlands, 345 tons, $18,854. No change in grand totals.

[2] Less than 1 ton.

Exports.—Effective February 3, 1941, Federal licenses were required for all exports of potash salts. Shipments by producers outside the immediate American market, which is considered to include continental United States, Puerto Rico, Hawaii, Canada, and Cuba, were relatively small, as the need for supplying domestic requirements in the absence of imports left little surplus for export. The bulk of potash fertilizer shipments to countries other than those listed above were drawn from consumers' or speculators' stocks. During the early months of the year Japan continued to receive sizable cargoes, although less than in 1940.

Potash materials exported from the United States, 1937–41

break of hostilities in Europe in 1939; hence, there has been a dearth of information on world production of potash in recent years. The appended table represents a compilation of all official statistics on production that have been issued for 1937 to 1941.

FOREIGN DEVELOPMENTS

Australia.—Reports from London state that potash resources in Australia are being explored through the Commonwealth Council for Scientific and Industrial Research. Deposits in the bed of Lake Campion in Western Australia are estimated to contain 2,000,000 tons of alunite, from which 250,000 tons of potassium sulfate could be obtained. Plans are said to include dredging the deposit and constructing a plant to produce 200 tons per week of sulfate or chloride. This would satisfy demands of the Commonwealth, which normally imports around 12,000 tons of potash salts a year. Stocks accumulated in anticipation of interrupted imports are believed to be adequate to last until production can start. The possibility of applying American processes for the production of alumina and aluminum metal from alunite likewise is being studied.

Chile.—Potash production in Chile has been a relatively unimportant offshoot of the sodium nitrate industry. A mixture of sodium and potassium nitrates containing about 14 percent potash found favor in the American market during the last war and earned a profit for the manufacturers. Shipments have continued ever since and in 1941 constituted about two-thirds of the potash fertilizer salts imported. A significant new development is foreshadowed in the recent announcement that the Chilean Government has contracted with the Compañia Salitrera de Tarapacá y Antofagasta (nitrate producers) to organize a company to be known as Sociedad Chilena Explotadora de Potasa to work potash deposits in the Salar de Pintados, in the Province of Tarapacá near Iquique. Plans are said to call for immediate construction of a plant to produce 30,000 tons of refined potash salts a year.

France.—No longer a producer of potash after the loss to Germany of the Alsatian mines in 1940, Unoccupied France is receiving its potash supplies from Spain, doubtless with the consent of German authorities and probably due to transportation difficulties from Alsace. Shipments from Barcelona enter at the port of Cette on the Mediterranean. Rumored plans called for delivery of about 50,000 tons in 1941, but it is believed that less than this amount actually was supplied.

Germany.—The potash mines in Alsace, formerly German-owned but operated by the French Government after the Treaty of Versailles until retaken by the Germans in 1940, are believed to have been returned to their original owners for reincorporation into the German industry. It is not known what disposition has been or will be made of the privately owned Mines de Kali Sainte Thérèse. It is reported that they are being operated by a German company organized for the purpose, but it appears that the French company is being kept alive by the Germans. It is understood that considerable difficulty has been experienced in reestablishing the Alsatian industry. When this operated under French control nearly half the output was ex-

ported through Belgian or Netherlands ports. These outlets now are closed, and transportation in other directions is difficult. Shortages likewise are felt in supplies, equipment, and manpower. Similar problems face the industry in Germany proper. It is believed that little, if any, German potash is being shipped overseas, and it is doubtful whether increased use at home and in the German-dominated countries in an effort to obtain maximum crop production can offset the loss of overseas trade. As previously reported, the big potash companies have attempted to stabilize their operations by branching out into other fields, such as the production and refining of oil, the manufacture of synthetic motor fuels and other byproducts from coal, and the production of magnesium metal and magnesium products.

Under agreements with the German-French Potash Cartel, entered into in 1935 by Spanish producers, Germany delivered several hundred thousand tons to foreign buyers for the account of Spanish producers in 1936, 1937, and 1938, when the Spanish mines were closed by the civil war. The agreements were understood to provide that Spanish producers would be entitled at a later date to indemnification or an increased share in the export market. The Spanish companies are controlled by French and Belgian interests, but both countries are under German domination. There are indications of German interest in rehabilitation of the Spanish mines that resumed production in 1939 but are still far below their maximum pre-war output. If Germany could help to build up Spanish exports, it would serve the double purpose of liquidating indebtedness and conserving foreign markets, insofar as that may be possible.

Palestine.—The chairman of Palestine Potash, Ltd., in his statement to stockholders at the annual meeting November 12, 1941, reported that progress in output and sales had continued without interruption, despite shipping difficulties and delays in obtaining plant and materials brought about by prevailing conditions. From the start of operations, costs decreased steadily until the outbreak of war. Since then there have been certain inevitable increases. £250,000 spent in the 3 years 1938–41 on plant, machinery, and buildings increased output, rationalized production, and maintained for the company its status as what is believed to be the cheapest potash producer in the world. Although profit on trading increased from £199,000 in 1939 to £292,000 in 1940, provision for excess-profit taxes, participation in profits by the Governments of Palestine and Transjordan, and United Kingdom taxation reduced the net profit from £80,254 in 1939 to £15,773 in 1940. Since the outbreak of war, information regarding production and shipments has been considered confidential.

Spain.—Production of potash was resumed in 1939 after the close of the Spanish Civil War, which interrupted operations in 1936. The properties were rehabilitated slowly under difficult conditions. The damage suffered by mines and plants is reported to have been largely from disuse rather than from sabotage. Although no definite information is available regarding the present scale of operations, it is believed that the three operating companies—Minas de Potasa de Suria, Potasas Ibericas S. A., and Union Española de Explosivos—are producing refined salts at the rate of 100,000 to 120,000 tons of K_2O per year. Imports into the United States from Spain in 1941 included 13,655 short tons of muriate. One shipload consigned to

497779—43——94

the United States in December was reported to have been recalled and unloaded at Lisbon. The American market is not particularly attractive to the Spanish exporters because prices are considerably lower than in other markets and high ocean freight and insurance rates leave little profit. Union Española de Explosivos is export selling agent for all three companies, and sales in the United States are handled by the French Potash & Import Co., formed to take over French business when war between France and Germany caused dissolution of the joint sales agency N. V. Potash Export My. Spanish consumption of potash has increased greatly and may now be as much as 40,000 tons of K_2O a year. Spain is supplying potash to Unoccupied France and is reported to have delivered a substantial tonnage to England. It is understood that shipments will be made only on navicerts from Britain and Germany.

MICA

By Paul M. Tyler and K. G. Warner

SUMMARY OUTLINE

SUMMARY

After making new records during 1940, the demand for all kinds of mica continued to increase in the United States until the fourth quarter of 1941, when curtailed manufacture of civilian goods and other conservation measures temporarily offset the growing needs of war industries. Domestic production of sheet mica responded to the increased demand with a 64-percent expansion, and imports increased 31 percent. After Pearl Harbor, estimates of 1942 requirements were boosted to 5,000,000 pounds for strategic block mica alone; but even this high figure, calling for more than doubling normal world production, was viewed with complacency in the expectation that with Continental Europe and Japan out of the market the United States could procure about 50 percent of its expanded needs from British India, 40 percent from Brazil, and 10 percent from other sources (chiefly domestic).

Stocks of splittings at the year end were highly satisfactory, particularly in view of the reduced civilian demand; and, with the possible exception of condenser mica, stocks of block mica in private hands and in Government stock pile were fairly well maintained. Not until Japanese successes in the Pacific threatened to cut off further deliveries from India did fears of an acute shortage of mica become at all general.

The rapidly expanding output of combat equipment created an unprecedented demand for strategic mica, which is defined as block and punch mica of better than heavy-stained quality, free of mineral inclusions (black or red spots, stains, or streaks), cracks, pinholes, cross grains, reeves, and ribs and relatively free of clay staining. It must be hard, clear, reasonably flat, and capable of being evenly and easily split into laminations or sheets of uniform thickness over the entire area, yielding sheets at least 1 by 1 inch in size. The heaviest demand is for 1½- by 2-inch, 2- by 2-inch, and 2- by 3-inch sizes. The principal strategic applications are for making parts of radio transmitting and receiving equipment, aviation magneto condensers and spark plugs, and electrical power development machinery.

To stimulate domestic production, the War Production Board took steps to finance the purchase of strategic mica through the Metals Reserve Co., a subsidiary of the Reconstruction Finance Corporation. Miners were urged to attain maximum output; and, because of the complexities of mica classification, instructions on grading and trimming were prepared.

Splittings, nearly all of which are obtained in India, are also important to the war program. Consumption of splittings, which are used for making a great variety of "built-up" mica products, increased 48 percent in 1941 compared with 1940.

Figures for scrap and ground mica are of lesser significance because they are not regarded as strategic.

The accompanying table of salient statistics portrays outstanding features of the mica industry during the past 5 years.

Salient statistics of the mica industry in the United States, 1937–41

	1937	1938	1939	1940	1941
Domestic mica sold or used by producers:					
Total uncut sheet and punch

Value	$216,858	$183,889	$226,364	$191,550	$280,810

[1] Includes mica recovered from kaolin and mica schists, as follows 1937, 10,536 tons, $149,931; 1938, 6,550 tons, $86,602; 1939, 10,011 tons, $108,899, 1940, 9,674 tons, $138,148, 1941, 15,583 tons, $185,486.

[2] Exclusive of a nominal quantity of splittings produced in the United States and South America.

DOMESTIC PRODUCTION

Sheet mica.—Production of sheet mica in the United States increased sharply in 1941 to an all-time record total of 2,666,453 pounds (valued at $566,858). This compares with a previous record quantity of 2,476,190 pounds worth only $283,832 in 1910. The value of the 1941

output, however, fell short of the record established in 1917 and of 1918. In the former year the output was only 1,276,533 pounds, but it was valued at the high figure of $753,874; the 1,644,200 pounds produced in 1918 were valued at $731,810.

As usual, most of the 1941 output was punch mica. Production of this material increased to 2,342,237 pounds valued at $206,947, representing an increase of 67 percent in quantity and 78 percent in value over that of the preceding year. Although the production of sheet larger than punch showed a smaller percentage increase in quantity, it increased much more in value, the 1941 total being 324,216 pounds worth $359,911 compared with 220,132 pounds and $175,598 in 1940, and only 147,953 pounds and $99,756 in 1939.

About 61 percent of the punch and 54 percent of the larger sheet were produced in North Carolina in 1941. Sales of punch in that State were 70 percent and in the United States as a whole 67 percent greater in 1941 than in 1940. Sheet-mica sales, however, increased only 13 percent in North Carolina, whereas the increase for the country as a whole was 47 percent. New Hampshire, the second-largest producing State, made a large percentage increase in output, as did several of the smaller producing States. In Connecticut, a small reduction in the output of punch was more than offset by a 133-percent increase in yield of sheet.

Mica sold or used by producers in the United States, 1925–41

[1] Includes small quantities of splittings in certain years.
[2] "Uncut mica larger than punch and circle" and scrap for New Hampshire included with "Other States."
[3] 1940: Alabama, Arizona, California, Colorado, Georgia, Maine, New Mexico, New York, South Carolina, South Dakota, Vermont, and Virginia, includes also "Uncut mica larger than punch and circle" and scrap for New Hampshire; 1941. Alabama, Arizona, California, Colorado, Georgia, Maine, New Mexico, New York, Pennsylvania, South Carolina, South Dakota, Vermont, Virginia, and Wyoming.

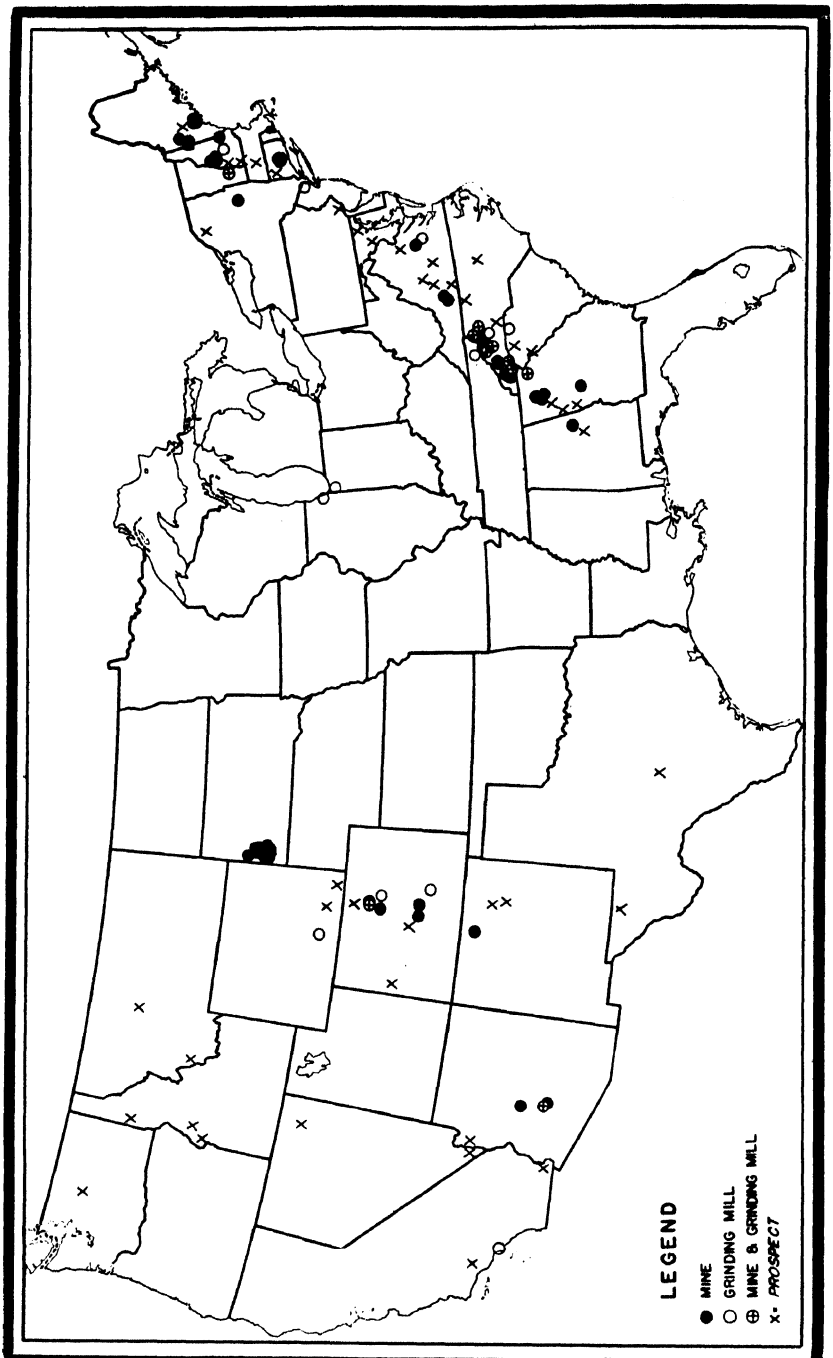

FIGURE 1.—Mica mines, prospects, and grinding mills in the United States.

In North Carolina more than 16,500,000 pounds of sheet and punch mica have been produced since 1868 in the 250-square-mile area around Spruce Pine, N. C. T. L. Kesler and J. C. Olson of the Geological Survey report that mica or feldspar has been mined in this area from more than 500 pegmatite bodies. These bodies, some of them more than 100 feet thick, are most closely associated with alaskite (a variety of granite) and occur both in the alaskite and in adjacent metamorphic rocks. Commercial mica is commonly localized in irregular shoots or "streaks" and even in these shoots is distributed so irregularly as to preclude adequate prospecting or development in advance of mining. From field studies and analysis of production records for 131 mines, these geologists concluded that systematic planning of mica mining in this area as a whole could easily raise the output of relatively clear sheet mica to 90,000 pounds a year, perhaps several times this amount. Careful measurements were made by E. L. Hall of the National Bureau of Standards of 196 samples collected from 109 mica mines and 15 feldspar mines, and samples from 71 mines were found to have power factors low enough to meet the rigid requirements of radio-transmitter and high-tension magneto-condenser manufacturers.

Scrap mica.—After a slight set-back in 1940, the production of "scrap mica" from domestic sources jumped to 32,500 short tons valued at $442,789, reflecting a sharp upturn in the rising demand curve and a reduction of imports from overseas. In addition to mine scrap, these figures include mica, recovered from washing kaolin or kyanite or by milling schist, amounting to 15,583 tons valued at $185,486, compared with 9,674 tons valued at $138,148 in 1940 and 10,011 tons valued at $108,899 in 1939.

Ground mica.—The production of ground mica likewise resumed its upward trend, advancing to 43,419 tons valued at $1,532,351 compared with the previous record of 30,924 tons worth $1,156,333 in 1939. Of special interest is the increase in output of wet-ground mica, which remained almost stationary around 3,000 tons a year until 1937, when it began to rise irregularly but rapidly. Following its rapid rise during the early 1930's, when other industries were in the doldrums, the output of dry-ground mica was seemingly stabilized after 1936, but in 1941 it also jumped into new high ground. Demand was active in all consuming outlets, and, although demands of the roofing industry accounted for the bulk of the increase, consumption in paint and miscellaneous uses showed the largest percentage gains.

The history of the scrap- and ground-mica industries over a series of years is indicated in figure 2.

Ground mica sold by producers in the United States, 1937–41, by methods of grinding

Year	Dry-ground [1]		Wet-ground		Total [1]	
	Short tons	Value	Short tons	Value	Short tons	Value
1937	21,150	$457,879	6,095	$381,933	27,245	$839,812
1938	19,757	466,959	7,329	457,595	27,086	924,554
1939	23,222	547,539	7,702	608,794	30,924	1,156,333
1940	21,809	515,930	6,175	500,698	27,984	1,016,628
1941	31,914	733,559	[1] 11,505	[1] 798,792	43,419	1,532,351

[1] Includes mica from kaolin and schists; some from sericite schist included in wet-ground in 1941.

[1] Includes mica from kaolin and schist.
[2] Includes mica used for molded electric insulation, house insulation, Christmas-tree snow, manufacture of axle greases and oil, annealing, pipe-line enamel, plastic specialties, textiles, and other purposes.

The question as to whether ground sericite can be commercially designated as "ground muscovite" or even as "ground mica" is controversial. Ordinary muscovite, damourite or hydromica, and oncosine or pinite all have roughly the same composition. Sericite and metasericite may be classified as subvarieties of damourite, which in turn is a variety of muscovite distinguished by small scales, which are less elastic, unctuous, and pearly to silky in luster. The term "sericite" is derived from the Greek word for "silky." It has been contended that the original sericite from the silky schist of the Nerothal near Wiesbaden was derived from the alteration of feldspar; some geologists insist that sericite is a secondary mineral and thus distinguishable from ordinary muscovite, which is primary.

Sericite is ground much more easily than ordinary muscovite or other forms of mica. Roughly prepared, it has been used extensively for roofing, as a refractory, in foundry facings, and as decorative

material (for example, Christmas-tree snow). In 1941, sericite from a gold mine at Kershaw, S. C., was actively marketed. This new product, which requires only light disintegration and washing to yield a 325-mesh product, is used mainly for casein paint. Although selling for less than half the price, it is claimed to be better than ordinary water-ground mica in varnishes and certain other protective coatings because it lacks sheen yet retains the fish-scale form, which is one of the superior properties of wet-ground compared with dry-ground muscovite.

Mixing ground mica (325-mesh) with aluminum bronze powder to save aluminum has produced a paint having superior resistance to salt air and chemical fumes. Micronized mica, which is produced under exclusive franchise by one North Carolina company, yields a product marketed as 100 percent passing the equivalent of 3,000-mesh and used as an extender or filler in paints and plastics. Biotite, similarly ground, is employed in lubricating greases, leather finishes, and other special applications. Alone or combined with graphite, increasing quantities of ground mica are used in foundry facings, parting base, and core or mold washes.

TOTAL CONSUMPTION OF BLOCK AND SHEET MICA

Economists unfamiliar with the mica business are amazed to find that it is impossible to establish a satisfactory statistical picture of the industry. By eliminating scrap and considering the production and trade in ground mica as a distinct industry, the problem is clarified; a further simplification is to segregate splittings and built-up mica, but even when the discussion is narrowed to uncut sheet or block mica, it is still impossible to give a satisfactory answer to the seemingly simple question as to how much is consumed in the United States.

During 1941, the consumption of virtually every class of mica increased greatly, but the principal increases were of the better qualities used for military radio and magneto condensers, airplane spark plugs, and other strategic uses. Monthly statistics of actual consumption and stocks of specified grades and qualities of block mica were first collected by the Bureau of Mines in July 1940, and these figures are summarized upon a quarterly basis in the form of bar charts in figure 3.

The statistics on domestic production of raw sheet or block and imports for consumption of all kinds of mica (manufactured as well as unmanufactured) other than scrap and ground mica are shown in the form of 5-year averages in an accompanying table. The sum of these figures tends to show that the average annual consumption of sheet mica, including imported manufactures, declined about 10 percent from 1925–29 to 1935–39. Actually, however, the total consumption was greater during the latter period, or at least the potential services rendered by the 6,038,958 pounds available annually during 1935–39 were greater than those afforded by the 6,672,519 pounds average total for 1925–29. This anomaly is due not only to the losses in manufacturing where parts of the sheet are trimmed away (in the same fashion that a suit of clothes weighs less than the material cut from the original bolt of cloth), but also to the difference in preparation of the so-called "uncut" sheets.

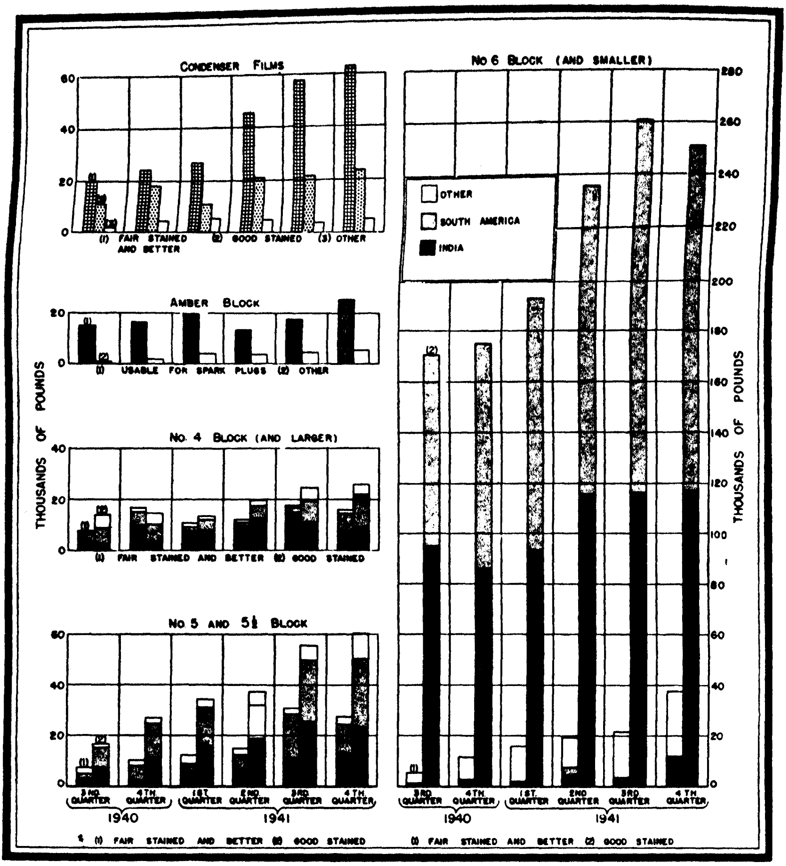

FIGURE 3.—Consumption of specified kinds of block mica in the United States, by quarters, July 1940 to December 1941.

Apparent consumption and changes in sources of supply of sheet mica (excluding scrap and ground mica), annual averages, 1925–29 and 1935–39

	Average quantity, in pounds		Average percent of total apparent supply	
	1925–29	1935–39	1925–29	1935–39
Domestic production (sales):				
Uncut punch	1,433,684	888,313	21.5	14.7
Uncut sheet larger than punch	405,400	252,411	6.1	4.2
Total production	1,839,084	1,140,724	27.6	18.9
Imports for consumption:				
Uncut block valued not above 15 cents	138,495	264,794	2.1	4.4
Uncut block valued above 15 cents	666,374	485,879	10.0	8.0

Cut or trimmed to size (sheet)	63,960	81,209	.9	1.3
Other manufactured sheet	31,928	4,261	.5	.1
Splittings	3,921,373	4,020,860	58.7	66.6
Built-up mica	11,305	41,231	.2	.7
Total imports	4,833,435	4,898,234	72.4	81.1
Grand total	**6,672,519**	**6,038,958**	**100.0**	**100.0**

Mica comes from the ground in irregular pieces, which are roughly sorted or "cobbed" to remove the bulk of the scrap or waste mica suitable only for grinding. The remaining crystals or blocks are split roughly ("rifted") into thicknesses that permit careful inspection and easy cutting (usually less than ⅛ inch). The next step is "trimming" or cutting away imperfections. In Bengal all edge imperfections are removed by sickle, which leaves an irregular and often indented outline. Madras mica is trimmed by knife or guillotine shears; the outline is much more regular, the edges being all straight, corners sharp, and re-entrant angles absent. Smaller sizes of Madras sheet may be knife-cut into "rounds," but all Madras is closely trimmed. According to Wierum:[1]

After trimming, the sheets are graded or sized, generally by the use of a template upon which each piece is laid. The horizontal and vertical lines of the chart that are at the greatest distance from a given corner, and that are entirely covered by the piece of mica indicate its "grade" number or size. The sized sheets then go to sorters, who determine the quality of each piece. They are the most responsible and the best-paid workers at an Indian mica plant. Frequently these men are able greatly to improve the quality by removing stained films from the interior of a sheet, thus making two or more thinner pieces, but of perhaps double the value per pound with a loss of only a small fraction of the original weight.

Practically all countries except the United States and Canada follow approximately India's methods of trimming sheet mica, but few of them use the meticulous care of the native Indians or offer a product so entirely free from surface and edge imperfections. There is one peculiarity of the Bengal trim, however, that is not generally imitated in other producing countries, largely because it is unnecessary unless splittings are to be made from the sheets. It is the beveling of the edges, produced by holding the native sickle at a sharp angle when trimming the sheet.

The wastage in ordinary thumb-trimmed domestic mica has been estimated at fully 35 percent more than in Indian knife-trimmed. The waste in respect to domestic punch is much greater. One large consumer reports using about 350 pounds of North Carolina punch mica to make 100 pounds of washers and disks and approximately 155 pounds of domestic punch for 100 pounds of other die-cut products. A rough average for knife-trimmed mica is 150 pounds of raw mica for 100 pounds of stampings. In respect to condenser films, due to additional losses in splitting it takes less than 200 pounds of imported and 300 to 400 pounds of domestic condenser splits to make 100 pounds of finished rectangular films. South American mica in general is trimmed less closely than Indian but more closely than domestic.

In Minerals Yearbook, 1940, an attempt was made to show the domestic consumption of sheet mica in 1937 by uses. Of an estimated total of 2,600,000 pounds used in the United States in that year, 43 percent was used for washers, disks, and other small stampings; 29 percent for radio-tube parts; 19 percent for electrical appliances; 6 percent for condensers; 2 percent for aviation spark plugs; and less than 1 percent for miscellaneous uses. An estimate for July 1941 shows only 26 percent for washers, etc.; 35 percent for radio-tube parts; 10 percent for electrical appliances; 23 percent for condensers; 5 percent for spark plugs; and 1 percent for miscellaneous uses.

The foregoing figures include allowances for block-mica equivalents of imported condenser splits and involve other broad assumptions but tend to confirm the increasing importance of radio condensers

[1] Wierum, H. F., The Mica Industry: U. S. Tariff Commission Report 130, 2d ser., 1938, pp. 51-52.

and tubes for military communications and aviation spark plugs relative to consumers' durable goods and even industrial equipment. A further effect of this wartime change in the pattern of demand is the relative increase in requirements for the better grades of mica, notably condenser mica. Approximately half of the consumption of condenser mica in 1941 was of fair-stained or better qualities, chiefly sizes 5 and 5½, for transmitter or high-tension condensers.

Figure 4 summarizes graphically the situation with respect to imports and domestic production. The tremendous and growing importance of imported mica splittings is clearly shown in this chart. As regards block mica, because no adjustment is made for the large

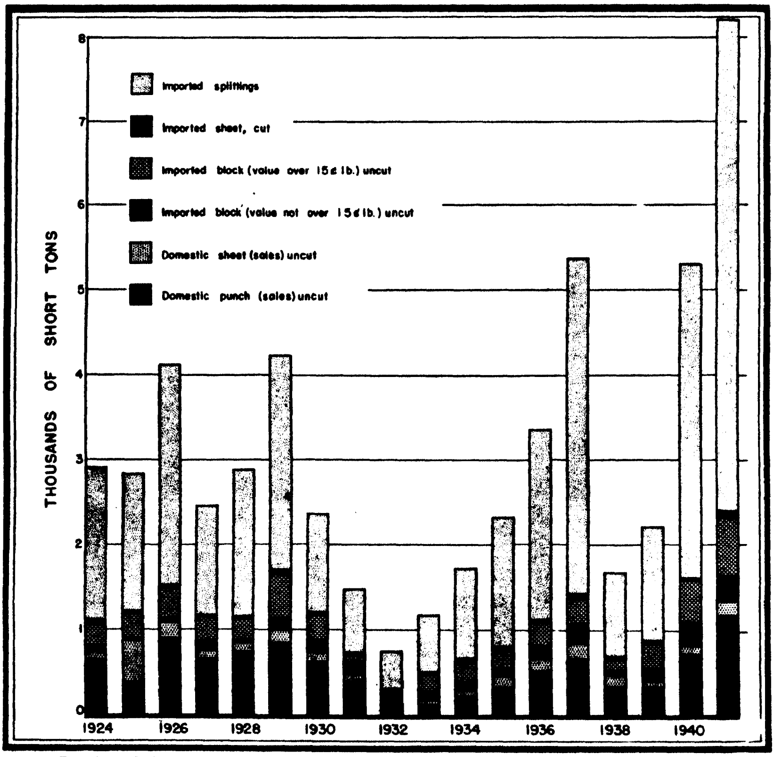

FIGURE 4.—Block and sheet mica (cut) and splittings imported for consumption in the United States, and sales of domestic sheet and punch mica, 1924-41.

wastage due to the rough trimming of domestic mica, the relative importance of domestic production is much less even than the chart indicates. The comparison probably would more nearly approximate actual manufacturing conditions if the quantities of domestic punch were reduced at least one-half and possibly two-thirds.

MICA SPLITTINGS

Notwithstanding a large increase in consumption over the 1940 all-time record, industry stocks of mica splittings increased during 1941, and a sizable Government-owned stock pile was created. Consumption of amber splittings increased even more rapidly than that of

muscovite splittings during the latter half of 1940; but before the end of the first quarter of 1941 stocks were depleted, and prospects of obtaining supplies from Madagascar worsened so that consumption of such splittings began to decline sharply. Consumption of muscovite splittings reached a peak in May 1941 but rose to even higher levels in October, after which various voluntary conservation measures and the prospective curtailment in manufacture of civilian goods reduced the demand for built-up mica and consequently the consumption of splittings of all categories. No. 6 loose splittings represented 85 percent of the total consumption of muscovite splittings during the fourth quarter of 1940 and 80 percent of the total during the corresponding period of 1941. Even in this group, the proportion of first and second qualities increased sharply, whereas that of third quality diminished, but the trend to use higher grades was more marked in respect to larger splittings, especially those that were book-packed.

Production of splittings in the Western Hemisphere has been confined largely to Canada. Phlogopite tends to split somewhat more readily than muscovite, and, in addition to the hand-made splittings produced in Quebec, variable but in some years substantial quantities of Canadian phlogopite have been imported (under lower-duty brackets) and split mechanically. Serious consideration has been given to increasing this business, and additional equipment was installed in 1941 for this purpose. As Canadian experience indicated a definite correlation between aptitude for splitting mica and ability to execute fine needlework, consideration also has been given to establishing a mica-splitting industry based upon Brazilian block mica in Puerto Rico; but this plan has not materialized, and steps have been taken to expand the small production of splittings in Brazil. Still another proposal is to bring small Brazilian block mica to Mexico for splitting. Late in 1941, the mining of amber mica near Oaxaca, Mexico, attained some importance, and several hundred Mexicans were trained in the art of making splittings. They have shown more aptitude for this work than Brazilians or Anglo-Saxon workers, and, as wages in the small towns or villages are 1 peso or less than $0.25 a day, it would seem possible to expand the Mexican splitting industry to include Brazilian or even domestic muscovite.

Consumption and stocks of mica splittings in the United States, 1937–41, by sources, as reported by the consumers

Year	India		Canada		Madagascar		Total	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
Consumption [1]

[1] Exclusive of a nominal quantity of splittings produced in the United States and South America.

Beginning with July 1940 the Bureau of Mines began to collect monthly statistics of consumption and stocks of mica splittings by sizes and qualities for the information of all the defense agencies. The consumption figures are summarized graphically upon a quarterly basis in figure 5.

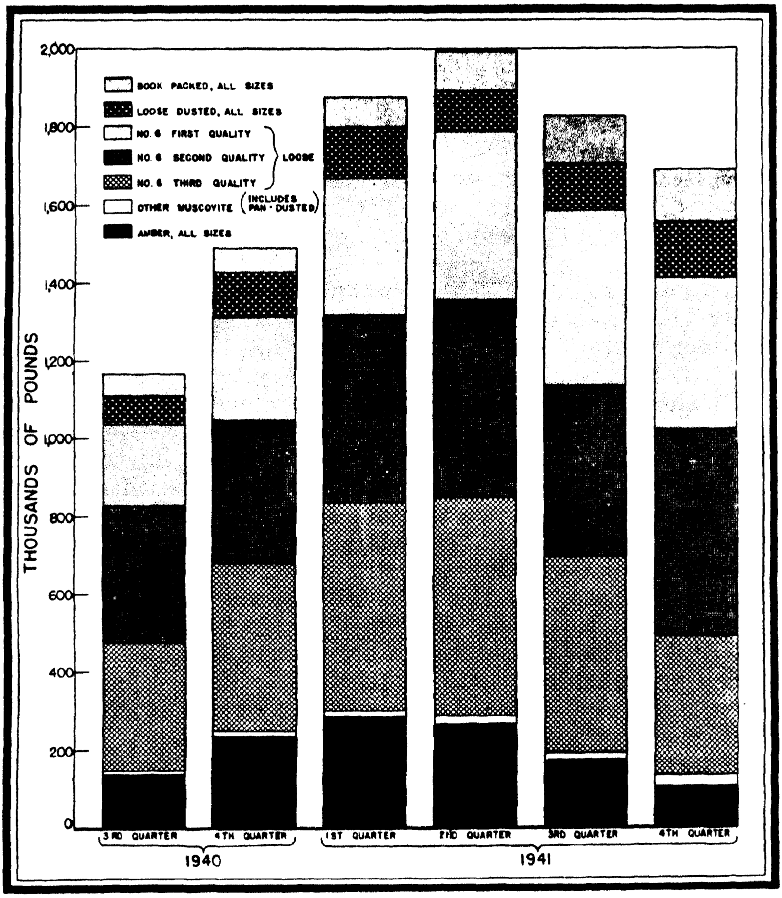

FIGURE 5.—Consumption of specified sizes and qualities of mica splittings in the United States, by quarters, July 1940 to December 1941.

BUILT-UP MICA

As indicated by the quarterly consumption figures for mica splittings shown in figure 5, factories handling built-up mica were operating virtually at capacity during the early part of 1941, but, as the growing shortages of metals and other materials brought about curtailment in the manufacture of electrical appliances and other consumers' durable goods and as some wartime substitution and conservation of mica began to take effect, demand for built-up mica diminished during the latter half of the year. Nevertheless, the total poundage for the year was 50 percent higher than the previous all-time record of 1940, and the value of the output was almost 40 percent higher.

Built-up mica produced in the United States, 1940–41, by kind of product [1]

Product	1940		1941	
	Pounds	Value	Pounds	Value
Molding plate	1,315,000	$1,410,000	1,873,822	$1,854,000
Segment plate	1,510,000	2,024,000	2,317,364	2,599,000
Heater plate	561,000	878,000	539,410	789,000
Flexible (cold)	330,000	383,000	705,532	754,000
All other (tape, etc.)	697,000	1,116,000	1,199,361	2,089,000
	4,413,000	5,811,000	6,635,489	8,085,000

[1] Partly estimated.

PRICES

It is generally conceded that, during the 1930's and for some time before, the broad trend of mica prices was upward, with prices of smaller and poorer kinds increasing relatively faster than those of the larger and better grades and sizes. Military requirements, however, have taxed the ability of the world's miners to supply mica of qualities equal to India good-stained or better. Late in 1941, progressive curtailment in production of refrigerators and other electrical appliances for civilian use diminished the demand for ordinary electrical and stove mica, and even before that the demand for these lower grades did not keep pace with that for higher qualities. Consumer acceptance of Brazilian mica and to some extent of domestic mica also has tended to place mica from other countries more nearly on the same price levels as comparable Indian grades. The net result of these market forces has been to advance prices of all kinds of mica together in response to the much higher cost of ocean transportation and insurance on shipments from India.

During 1940, efforts to stimulate domestic production resulted in relatively higher prices for punch and circle mica on the theory that this was the bulk-line product and so would afford maximum encouragement to the miners, but in 1941 the prices of North Carolina punch remained almost stationary while those of sheet or pattern mica increased. Toward the end of the year, owing to the falling off in demand for washers and other die-cut or shear-cut mica for household-appliance manufacturers who were unable to get priorities on metallic parts, prices of all kinds of domestic electrical mica began to weaken, suggesting a definite reversal of the pre-war trends favoring No. 6 Indian good-stained and lower grades.

Quantitative comparisons of mica prices, especially over a period of years, are impaired by the flexibility of standards and the fact that prices quoted by different suppliers, even on the same day, may vary widely. In December 1941, for example, one importer quoted two classes of No. 6 first-quality loose muscovite splittings at 36 and 46 cents a pound, respectively, and during the latter half of 1941 an important consumer paid as little as 34 and as much as 47 cents for splittings of this same designation. Weighted averages of all purchases by this consumer advanced from 31.1 cents during the pre-war period July 1 to September 30, 1939, to 39.8 cents during the period July 1, 1941, to January 31, 1942—an increase of 28 percent. Another large consumer reported an apparent increase averaging

more than 30 percent (on a lower price range), whereas one leading importer reported an average advance of 35 percent and another 14 percent on this same large volume item. In respect to No. 6 seconds, an even larger tonnage item, reports from various users indicate a pre-war range of 18½ to 26 cents and 1941 year-end figures of 23 to 30 cents, indicating an average increase of at least 25 percent. Prices of Indian block mica are even more difficult to evaluate, as the spread between f. o. b. prices of different shippers tends to be greater even than that for splittings. Based upon the meager evidence available, it would appear that wartime increases in prices of standard good-stained Indian mica at the end of 1941 ranged from 10 to 25 percent, whereas those of Brazilian mica increased 25 to 50 percent or even more as a result of the narrowing of discounts on such mica as compared with similar Indian grades and sizes. In respect to the better grades of condenser splits, the increases were at least 50 percent and often more.

Before the war, the rupee depreciated in value from 37½ cents in 1936 to 30 cents in September 1939, but this was more than offset by higher prices in the bazaars, so that even in United States currency the mica price trend during that period was upward. After the outbreak of hostilities and throughout 1940 and 1941, rupee exchange remained steady while freight and insurance advanced. Based upon the net mica content of all shipments, ocean freight was equivalent to about 6 mills a pound until September 1939 but rose to 17 mills at the end of 1941. War risk and marine insurance, which before the war was 0.25 percent from Calcutta to New York, after Pearl Harbor jumped to 8 percent by way of Cape of Good Hope and 10 percent across the Pacific. Even as late as the early summer of 1941, the insurance rates on shipments in United States vessels were only 1.5 percent via the Cape and 0.5 percent via Panama or Transpacific. On shipments from Brazil, war-risk insurance was 0.10 percent before Pearl Harbor, after which it jumped to 1.5 percent.

FOREIGN TRADE [2]

Imports.—In 1941 the total imports of all kinds of mica increased to 8,300 short tons valued at $4,415,031 compared with 7,688 tons valued at $2,484,128 in 1940. Waste and scrap phlogopite imports nearly doubled, but imports of other waste and scrap declined to a mere fraction of their 1940 volume. Imports of untrimmed phlogopite declined moderately, while those of the higher grades of sheet mica increased substantially. Further details on imports by kinds and sources of origin are indicated in the following tables.

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Mica imported for consumption in the United States in 1941, by kinds and by countries

WORLD PRODUCTION

Owing to disturbed conditions throughout the world, data on production in foreign countries are scanty. The following table presents available figures.

World production of mica, 1937–41, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1937	1938	1939	1940	1941
North America:

[1] In addition to the countries listed, mica is also produced in Australia (Queensland and New South Wales), Eritrea, Kenya, and U. S. S. R., but data on production are not available.
[2] Data not available.
[3] Includes following quantities recovered from kaolin and schists 1937, 9,558 tons; 1938, 5,942 tons, 1939. 9,082 tons; 1940, 8,776 tons, 1941, 14,137 tons.
[4] Rail and river shipments.
[5] Official estimate
[6] Less than 1 ton.
[7] January to June, inclusive.

SALT

By F. E. Harris and K. G. Warner

SUMMARY OUTLINE

SUMMARY

Total salt production in 1941, which aggregated 12,720,629 short tons valued at $33,620,376, increased 23 percent in quantity and 27 percent in value compared with 10,359,960 tons valued at $26,474,619 (revised figures) in 1940. Of the total in 1941, salt in brine increased 27 percent, evaporated salt 20 percent, and rock salt 16 percent. The unit value per ton of the total salt increased from $2.56 (revised figure) to $2.64.

Increased supplies of various kinds for waging war required larger quantities of salt of all classes—a fact confirmed not only by the following table of salient statistics but by figures obtained regarding uses of salt. Although the import statistics for 1941 given below cover only 9 months of the year, they indicate a declining rate. Exports likewise declined; however, they maintained the favorable trade balance that has existed for some years past.

Salient statistics of the salt industry in the United States, 1930–34 (average), 1935–39 (average), and 1940–41

	1930-34 (average)	1935-39 (average)	1940	1941
Sold or used by producers:				
Manufactured (evaporated) short tons	2,251,226	2,507,374	2,782,741	3,330,106
In brine do	3,333,391	4,205,587	[1] 5,311,671	6,771,436
Rock salt do	1,822,889	1,947,254	2,265,548	2,619,087
Total:				
Short tons	7,407,506	8,660,215	[1] 10,359,960	12,720,629
Value [2]	$22,331,641	$23,405,612	[1] $26,474,619	$33,620,376

[1] Revised figures.
[2] Values are f. o. b. mine or refinery and do not include cost of cooperage or containers.
[3] Includes salt in bags, sacks, barrels, or other packages: 1938, 93 tons valued at $673; 1940, 6 tons, $12.
[4] Figures cover January to September, inclusive.
[5] Figures not available for publication.

The accompanying graph (fig. 1) illustrates how strikingly the great demand on the chemical industries affected the curve that represents the quantity of salt in brine produced and used in 1941. The index for salt in this category paralleled very closely the index of industrial activity throughout the period graphed (1935–41) and during 1941 accompanied the rising index of general business, passing it by 5 points. The curve of the combined quantity of evaporated and rock salt produced or sold was not quite so spectacular in its progress. In 1935 this salt of commerce began at a higher level and rose until 1937, but thereafter, in common with salt in brine and general business, it dropped and reached a low point in 1938. However, this drop was in the nature of a sag rather than a sharp decline, for it was still 8

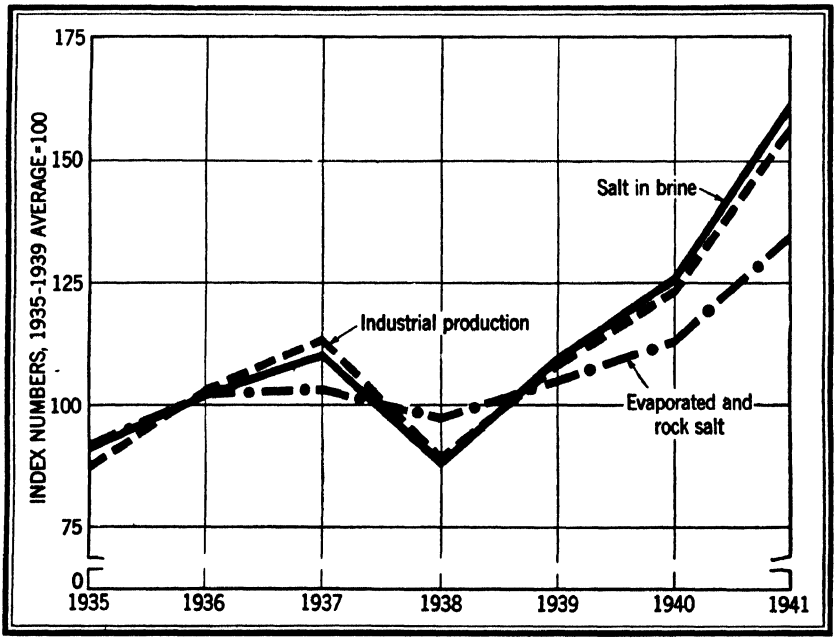

FIGURE 1.—Index of salt used in brine and of evaporated and rock salt compared with Federal Reserve Board index of industrial activity, 1935–41.

points above general business and 9 above salt in brine. From 1938 on it rose steadily, and although in 1941 it failed to attain the height of general business by 22 points its tonnage was the highest in history.

In numerous sections of the country wages increased as much as 13 to 45 percent. In some localities labor was scarce or not available. Fuel costs in one area increased as much as 60 percent. Bags and other packaging material cost considerably more. Where producers had difficulty in obtaining the required materials with which to work and could not make necessary repairs on their plants their output declined. Those who experienced a combination of all these difficulties plus competition—which precluded higher prices—said the profits in 1941 were negligible.

In Puerto Rico the imposed tax of 1 cent per pound of salt sold prevailed until August 12, 1941, when it was repealed.

PRODUCTION

The output of salt from mines, wells, and ponds in the United States was reported to the Bureau of Mines by 83 plants of 65 companies in 13 States and Puerto Rico for 1941 compared with 83 plants of 66 companies that reported for 1940.

Production by States.—In 1941, as in years past, Michigan ranked first in total production of salt, as well as of evaporated salt, and New York led in rock-salt production.

Salt sold or used by producers in the United States, 1939–41, by States

State	1939		1940		1941

Methods of manufacture.—Evaporated salt is manufactured either from natural brine of wells and ponds or by forcing water into salt beds and withdrawing it. The brine is evaporated by one of several methods. Salt evaporated in open pans or grainers is flaky and differs physically from the resulting grains of other methods. It is commonly known as flake salt and in the industry as grainer salt, and it is classified on standard lists as "medium" salt, being popular for certain food uses. Salt quoted on the market as vacuum fine is evaporated in vacuum "pans," which are mainly upright cylinders in single or multiple "effects." The product is a fine salt classified as evaporated granulated. Most of it is used for table salt. Solar salt is the product of sea water or inland playas. After the salt water goes through a series of settling ponds the salt is harvested. It may then be treated further in vacuum pans to produce fine table salt, or it may be screened and sized. The coarse salt is employed for industrial purposes for which rock salt may be used. Rock salt is mined or quarried and is crushed and sized for industrial uses. In some deposits it is pure enough for table salt after crushing and screening.

Salt sold or used by producers in the United States, 1940–41, by methods of manufacture

Method of manufacture	1940		1941	
	Short tons	Value	Short tons	Value
Evaporated:

	2,782,741	16,828,471	3,330,106	19,780,056

[1] Includes a quantity of salt contained in brine for chemical use reported as evaporated salt with value as evaporated salt.
[2] Included under "Other States."
[3] 1940. Colorado, New Mexico, Oklahoma, Texas, and Utah; 1941: Colorado and New Mexico.

Rock salt.—The output of rock salt came from 22 plants in 8 States—chiefly New York, Louisiana, Kansas, Michigan, and Texas, in order of output; California, New Mexico, and Utah also produced some.

Rock salt sold by producers in the United States, 1937–41

Year	Short tons	Value	Year	Short tons	Value
1937	2,030,432	$6,447,648	1940	2,265,548	$7,384,839
1938	1,901,861	6,252,081	1941	2,619,087	8,761,827
1939	2,035,157	6,496,807			

Pressed blocks.—The output of pressed blocks from both evaporated and rock salt totaled 239,032 short tons valued at $1,966,305 in 1941 and increased over 1940. This does not include blocks that may have been made from salt bought on the open market but is confined to

sales by the original producers of the salt. As in 1940, 19 evaporated-salt plants and 8 rock-salt plants made the output of pressed blocks reported.

The Department of Agriculture says that the quantity of salt required by cattle varies according to forage and other conditions but that it is well to allow an average of 2 pounds a month per head for all cattle 1 year old and over. For calves, it was concluded that 0.5 to 1 percent of salt may be added to the grain mixture to supplement the ration and that it may also be kept in a box available to the calves at all times. The average for sheep is about 1 pound a month. For mules and draft horses, some of the tests showed that the average consumption a month was 3.4 pounds; heavy labor and warm weather influence the requirements so that under such conditions they consumed almost twice that average. Practical experience showed that unless the salt lost by sweating was replaced the animals soon exhibited signs of excessive fatigue.

Pressed-salt blocks sold by original producers of the salt in the United States, 1937–41

Year	From evaporated salt		From rock salt		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1937	120,061	$966,812	28,981	$240,251	149,042	$1,207,063
1938	136,699	1,116,272	36,258	281,109	172,957	1,397,381
1939	152,121	1,136,527	39,242	263,300	191,363	1,399,827
1940	152,267	1,193,237	40,171	282,435	192,438	1,475,672
1941	182,331	1,505,040	56,701	461,265	239,032	1,966,305

Salt content of brine.—In 1941, as in the past few years, the salt of brine registered the greatest increase in output; most of it is utilized in the manufacture of chemicals. The Federal Reserve index shows that production of chemicals in 1941 averaged 137 (1935–39=100) compared with 115 in 1940, 102 in 1939, and 96 in 1938. Bureau of Mines statistics indicate that salt of brine was 53 percent of the total salt produced in 1941 and was supplied by 10 plants in various parts of the United States.

USES

As is well-known, there is no scarcity of this most commonly used chemical raw material—salt. Furthermore, producers of the raw material can increase their capacity at a greater rate than the consuming industries can expand their plants. In 1941 the increased requirements for salt were satisfied even though many new chemical plants and additions to existing plants were built during the year.

Salt sold or used by producers in the United States, 1940–41, by classes and uses, in short tons

[2] Some salt used for dyes and organic chemicals included under "Chlorine."
[3] Included under "Other uses."
[4] Revised figures.

As may be seen in the accompanying table of uses for 1940 and 1941, large quantities of both evaporated and rock salt, as well as salt in brine, were used in manufacture of chemicals. The quantities so used increased in 1941—more of the increase being in evaporated than in rock salt.

As glass has been relied upon increasingly to replace some of the metals heretofore used in such articles as refrigerator and stove parts, cooking utensils and other items, and containers to substitute for tin cans, demands on soda-ash plants have increased tremendously. By the fall of 1941, soda plants were producing at full capacity and were beginning to run behind in deliveries. For making glass a dense type of soda ash is used; hence, there is said to be slight competition or none with most of the other industries for supplies because the majority of the latter use a light type. However, there was an important increase in requirements of soda ash for many uses.

The other element in salt—chlorine—has been prominent in the news in many ways, as here, too, the war has made huge additional demands. Control of its use had to be tightened even more than in 1940, and Government defense agencies issued several pronouncements in this regard. In July 1941, full priority control of chlorine became effective. New units for making chlorine were completed in 1941, but the chlorine situation is still tense. Large quantities are employed in high-octane gasoline for tanks and planes. The manufacture of munitions (particularly smokeless powder and explosives), parachutes, and antifreeze agents also consumes chlorine. The use of chlorine in water purification has increased tremendously in view of the necessity for providing ample water supplies in new industrial areas, army camps, air fields, and naval bases. Chlorine enters into the processing of great quantities of textiles for such quartermaster supplies as

sheets, blankets, and tents. Some chlorine is used in plastic parts of airplanes.

Chlorine is incorporated in sprays to fumigate stored grain against weevils and various bacteria, including the fermenting bacteria, which increased last year because of weather and other conditions. Some methods of cleaning clothes require in the aggregate a great deal of chlorine. Many metallurgical processes require chlorine in some form. Production of magnesium metal has soared in the last year. In the process utilizing sea water from the Gulf of Mexico, hydrochloric acid (made from salt) converts the magnesium hydrate into magnesium chloride. Much of the chlorine, however, is recycled through the process, and only limited quantities are required to counteract process losses. Plants now under construction in the West will manufacture magnesium metal by another method that will utilize chlorine gas from salt.

Iron and steel smelting and refining consume by far the greatest part of the salt used in metallurgical plants; zinc processing and vanadium roasting utilize minor quantities.

Salt serves a very important purpose in the treatment and softening of water, because in many industries the quality of the water bears directly on both the processing and the quality of the finished products. In some industries water is used in such large quantities that it constitutes one of the raw processing materials. For example, great volumes of treated water are needed in paper making. In textile manufacture, as well as in paper making, impure water may affect bleaching and dyeing. Moreover, hard water may have an injurious effect on sizing. In water softening the salt is not used direct but to regenerate the zeolite which is the real softener. Chlorine is the most important chemical, derived from nonmetallic minerals, that is employed in water purification. It also prevents collection of slime and corrects corrosive waters.

For years salt has been used for ice control on city streets and on the subsurface soil of railroad beds to prevent the tracks from heaving, as it reduces freezing. It is also used to stabilize clay and gravel roads. The method has proved particularly successful for such roads in cold climates, where freezing is the chief cause of cracks. Wartime economy directs special attention to the fact that cracks in highways are exceedingly hard on rubber tires and probably will be still harder on a synthetic substitute; the suggestion has been made that cracking of clay and gravel roads be taken care of by salt treatment. Literature has been cited and quotations given in past issues of Minerals Yearbook and other Bureau of Mines reports, bearing on the use of salt for stabilizing roads.

Information with regard to the use of salt in drinking water to replace the chloride lost from the human body through sweating when working in hot places was included in a Bureau of Mines report in 1941.[1] In this connection a large steel company that has supplied its workers with salt tablets beside the drinking fountains for 10 years now has in addition a drinking-water system in which the proper quantity of salt is introduced mechanically. Thus, cool salt water may now be obtained by the workmen from the drinking fountains.

[1] Harrington, D., and Davenport, Sara J., Review of Literature on Conditioning Air for Advancement of Health and Safety in Mines: Bureau of Mines Inf. Circ. 7128, 1941, p. 88.

Although the statistics available on uses include farm consumption in the general break-down, uses for farms alone are not separated. It is well-known, however, that the largest part of the salt reported under evaporated- and rock-salt blocks is consumed on the farms and grazing ranges of the country, but a certain quantity is also used in prepared feed. In addition, food preparation requires considerable quantities in canning and preserving vegetables, fruits, and meats, as well as in baking and other cooking. Weed killers and insecticides also require salt. The quantity used as fertilizer is not definitely known. Salt derivatives certainly are fertilizer ingredients, but the effect of the application of salt directly on soils is still being studied. A recent report [2] recommends the use of common salt as a fertilizer in certain cases. When used in mixtures of phosphate and potash, the growth of certain vegetables and the keeping and eating qualities of celery were improved. Some crops showed no benefit, and some were injured. In the absence of potash fertilizers, salt was not beneficial. The benefits obtained were attributed to the sodium and not the chlorine. The Na ion appeared to be needed almost as much for a nutrient in the NaCl-responsive crops as was the K ion.

MARKETING

The pattern of marketing the salt of commerce probably has changed most on the eastern seaboard. As no salt deposits are known to be nearer than about 200 miles from the coast, such industries as fish curing and others in coastal areas sometimes have found it easier to use salt imported mainly from the West Indies. The submarine menace has made it increasingly impracticable to use boats to haul salt from the islands, and seaboard consumers are turning to sources within the United States and Canada. This did not apply so much in the early part of 1941 but became evident by the end of the year, and increased shipping difficulties were experienced early in 1942.

Prices.—New York prices quoted on rock and evaporated salt were firm throughout the year; changes were made only once or twice during 1941 and then chiefly in the price for less than carlots. Bagged rock salt in carlots, delivered at New York, was quoted at $13.70 a ton from January until June, when the price rose to $14.20, where it continued throughout the remainder of the year; in less than carlots, rock salt was quoted at $15.50 to $16.10 at the beginning of the year and advanced to $16 to $16.60 in June and to $17 to $18 in October, at which prices it held the rest of the year. Bagged vacuum fine salt was quoted at $15.70 a ton in carlots throughout the entire year; in less than carlots it was quoted at $16.60 to $19.70, changed in June to $18.20 to $21, and rose in October to $19.40 to $23.20, which was unchanged to the end of the year.

Demand for salt was steady, and shipments moved regularly throughout the year. In September there was an unusually early demand from municipalities for salt for ice control.

Market grades and packages.—As reported in Minerals Yearbook, Review of 1940, a committee of salt producers and distributors, in cooperation with the Division of Simplified Practice of the National Bureau of Standards, completed a revision of standards recommended

[2] Harmer, Paul M., and Benne, Erwin J., Effects of Applying Common Salt to a Muck Soil on the Yield, Composition, and Quality of Certain Vegetable Crops and on the Composition of the Soil Producing Them: Jour. Am. Soc. Agron., vol. 33, 1941, pp. 952–979.

for market grades and packages of salt and published its recommendation (R70) in March 1941. Because of the shortage of certain packing material in 1941, it has been impracticable to apply these recommendations, even in the simpler form that was entirely satisfactory to the industry when received; therefore, they have had to be modified somewhat and some of them discontinued (at least temporarily). In the classification for the larger part of the United States, about 15 of the various sizes and packages have been dropped tentatively, chiefly pockets and cotton and burlap bags although certain square cartons and the oval tin packages also are included in the elimination. In the Pacific Coast area, 13 packages of various kinds and capacities have been dropped, whereas 2 new packages for table salt have been added.

Although neither new nor included in the listed standard sizes, salt may be obtained also in canners' tablets in sizes ranging from 10 to 150 grains. They are dispensed electrically or mechanically, at a rate of as many as 180 to 200 tablets a minute.

Distribution of sales.—A majority of the salt producers were engaged in interstate business. Most of the plants that did no interstate business were producers of solar-evaporated salt, but several rock-salt producers were in this category. Brine was used close at hand at most plants, and none could be considered interstate trade in salt. Movement of evaporated and rock salt into the various States is shown in the following table.

Distribution (shipments) of evaporated and rock salt in the United States, 1940–41, by States of destination, in short tons

[1] Includes production of Puerto Rico (evaporated salt); exports to Africa, Asia, Canada, Central America, Mexico, South America, West Indies, and other countries; shipments to Alaska, Hawaii, Puerto Rico, and Virgin Islands; and some shipments to unspecified destinations.

NEW SOURCES

With the exception of a few additional areas adjacent to those reported previously for Louisiana and Texas, no extensive discoveries of salt deposits in the United States have been reported beyond those shown on the map given in Minerals Yearbook, 1939 (p. 1358).

Directory changes.—Changes that have occurred since the directory of the salt industry was published in Minerals Yearbook, Review of 1940, are as follows:

New enterprises include the Desert Chemical Co. (4031 Goodwin Ave., Los Angeles, Calif.), which began operations at its Dale Lake plant at Twentynine Palms, Calif.; it made little production in 1941 but is looking to a larger output in 1942. The Dow Chemical Co. (Midland, Mich.) began to produce evaporated salt from Texas wells, for use electrolytically in the manufacture of magnesium metal from sea water at its Freeport (Tex.) plant. Bonneville, Ltd. (540 W. 7th St. S., Salt Lake City, Utah), began to produce solar-evaporated salt from the marshes at its Wendover plant in Tooele County, Utah. The Oklahoma Salt Industries Co. began to produce evaporated salt at its plant at Sayre, Beckham County, Okla. The Jefferson Island Salt Mining Co. (mine and refinery at New Iberia, Iberia Parish, La.) spent 9 months of 1941 building a new plant to replace the plant totally destroyed by fire in August 1940; in the last 3 months of the year the company mined and sold rock salt and pressed blocks made of rock salt, and it also made evaporated salt in vacuum pans but no pressed blocks from evaporated salt. The Avery plant of the International Salt Co. in Iberia Parish, La., added to its products in 1941 pressed blocks made from both rock and evaporated salt. The Morton Salt Co. (Chicago, Ill.) bought the rock-salt mine of the Crystal Salt Co. at Kanopolis, Ellsworth County, Kans., took possession in September 1941, and mined rock salt for the remainder of the year. The Crystal Salt Co. mined salt during the first 2 months of the year, then was idle for 7 months because of a caved shaft. Following the passage of a special leasing law by the Federal Government, the Metropolitan Water District of Southern California prepared to mine salt for treat-

ment of city water. In January 1942 the water district obtained two permits to mine salt from a large deposit on the public domain in San Bernardino County. None of the salt produced will be sold. Several salt companies were idle in 1941 because of too much rain or other reasons.

IMPORTS AND EXPORTS [3]

Salt imported for consumption in the United States, 1937–41, by classes

Year	In bags, sacks, barrels, or other packages (dutiable)		Bulk			
			Dutiable		Free (used in curing fish)	
	Short tons	Value	Short tons	Value	Short tons	Value
1937	802	$8,008	24,115	$80,248	21,079	$45,106
1938	654	8,228	17,849	45,897	[1] 21,010	[1] 47,800
1939	2,121	14,977	28,451	58,540	15,461	27,700
1940	1,024	6,601	16,413	59,029	[1] 12,965	[1] 25,174
1941 (Jan.–Sept.)	915	9,300	5,870	13,331	4,820	16,421

[1] Includes salt in bags, sacks, barrels, or other packages, as follows: 1938, 93 tons, valued at $673; 1940, 6 tons, $12; 1937, 1939, and 1941, none reported.

Salt imported for consumption in the United States, 1940–41, by countries

Country	1940		1941 (Jan.–Sept.)

MAGNESIUM COMPOUNDS AND MISCELLANEOUS SALINES

By Alvin Schallis and K. G. Warner [1]

SUMMARY OUTLINE

SUMMARY

The unprecedented activity of the United States in connection with the national defense program vastly increased the requirements for magnesia products during 1941. The manufacture of basic refractories was the chief use for magnesium compounds, but it is expected that before the end of 1942 their use in the manufacture of magnesium metal will be equally important. The Nevada magnesite industry is being rapidly expanded to huge proportions to supply in part requirements of magnesite for metal and refractory purposes. A flotation plant was installed at Chewelah, Wash., to increase production, reduce waste, and improve the quality of the products. Construction was begun in New Jersey on a plant to make refractory magnesia from sea water and dolomite, and other plants to use similar processes for supplying high purity magnesia to reduction plants were contemplated for the California coast. Several refractory plants that will use natural brines as sources of magnesia were being constructed during 1941, and additional plants of similar nature were planned. Dolomite, already the raw material in several plants manufacturing high-magnesia refractories, is the scheduled raw material for nine magnesium-metal plants now under construction. The further use of dolomite in the manufacture of magnesia refractories is likewise considered. Natural brines rich in magnesium compounds, which were discovered recently in Michigan and Texas, as well as the hitherto wasted magnesium chloride byproduct from the reaction between langbeinite and sylvite in New Mexico, were welcome sources of raw materials for proposed magnesium-metal plants. The output to be obtained from all of these new facilities, plus that from previously existing plants, will be used almost exclusively in the production of munitions.

The demand for salines followed the general trend of business to increased levels. The production of bromine and bromine compounds, largely used in the manufacture of the antiknock fluids added to gasoline, continued to increase during 1941. The new magnesium plant of the Dow Chemical Co. at Freeport, Tex., became another important

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

producer of Ethyl-Dow ethylene dibromide in 1941. The Desert Chemical Co. produced sodium sulfate products in its newly completed plant at Dale Lake, Calif., and the Washington Chemical Co. built a plant at Monse, Wash., to recover sodium sulfate from four deposits in that area. The need for additional soda ash production capacity has focused attention upon the natural sources of this commodity. A huge chemical industry based upon large deposits of trona recently discovered in southwestern Wyoming has been proposed, and exploratory work on this project is now under way. Substitution of enamel and ceramic ware for metals and alloys needed for war purposes greatly increased the requirements for borates. A prolonged strike at the American Potash & Chemical Corporation plant at Trona, Calif., caused a serious shortage of boron compounds during 1941, but the situation cleared after the men went back to work.

MAGNESIUM COMPOUNDS

MAGNESITE

Spurred by emergency conditions during 1941, domestic magnesite production advanced 12 percent over the 1940 production level to reach a new high of 374,799 short tons. The intense activity of the metallurgical industries and the greatly increasing demands for magnesium oxychloride cements taxed productive facilities of the magnesite producers to the limit. In addition to the unprecedented requirements of magnesite for long-established outlets, substantial quantities of magnesite were required for magnesium-metal production during 1941, and it is estimated that before the end of 1942 magnesite will be consumed in this application at the rate of more than 200,000 tons annually. Owing to the essential nature of these requirements and the threat of insufficient supplies, magnesite was placed on the critical list of essential materials on March 6, 1942.

Sales of dead-burned magnesite (not including refractory magnesia from sources other than magnesite) increased somewhat in 1941 over the 1940 level and totaled 135,956 short tons. Increased production activity of the steel industry was largely responsible for this increase, although new open-hearth furnace construction, increased application of basic refractories in steel production, and expanded industrial activity also played important roles. The use of refractory magnesia to replace imported refractory chromite has been considered, but it seems as yet to be merely a future possibility, inasmuch as adequate supplies of refractory-grade chromite are apparently readily available from Cuba.

Sales of caustic calcined magnesite rose sharply during 1941, reaching 30,225 short tons, an 86-percent gain over sales in 1940. Oxychloride cements for production of ship flooring consumed the greatest quantity of caustic calcined magnesite, although important increases in quantities used in rubber, rayon manufacture, and leather tanning were reported. Substantial quantities were likewise reported to have been used in the manufacture of magnesium metal; this use for caustic calcined magnesite will be vastly expanded in the near future by the construction of huge magnesium-metal plants in the West.

Salient statistics of the magnesite industry in the United States, 1937–41

	1937	1938	1939	1940	1941
Crude:					
Mined:

[4] Figures not available for publication.
[5] 1937–40: Includes dead-burned magnesite and refractory magnesia from sea-water bitterns; 1941: Includes dead-burned magnesite and refractory magnésia from sea-water bitterns, brucite, and dolomite.

The Northwest Magnesite Co. (Farmers Bank Bldg., Pittsburgh, Pa.) operated five or all of its six kilns at Chewelah, Wash., throughout 1941 and in December began to operate a new kiln having a daily capacity of 100 to 150 tons of dead-burned magnesite. A 300-ton-per-day flotation plant, which operates on a process developed in cooperation with the Bureau of Mines, was completed in June 1941, and test operation to determine the best commercial application of this equipment has since been under way. A preliminary geological report of the magnesite deposits of Stevens County, Wash., has been published by Bennett.[2] Figure 1 gives the location of magnesite and brucite mines, mills, and prospects.

The Westvaco Chlorine Products Corporation (405 Lexington Ave., New York, N. Y.) operated its Patterson and Newark plants (in California) at capacity during 1941. The Patterson plant processed magnesite mined at the Bald Eagle mine near Gustine, Calif., and at the Western mine above Livermore, Calif. (both owned and operated by the company), as well as ore shipped from Nevada. Magnesite from the Luning district—principal source of magnesite in Nevada—

[2] Bennett, W. A. G., Preliminary Report on Magnesite Deposits of Stevens County, Wash.: Washington Dept. of Conservation and Development, Div. of Geol., Rept. of Investigations 5, 1941, 25 pp.

was supplied by the Barium Products Co., Ltd., to the Newark (Calif.) plant of the Westvaco Chlorine Products Corporation until July 26, 1941. After that date the Sierra Magnesite Co.—a company in which the interests of the Todd-California Ship Building Corporation and the Westvaco Chlorine Products Corporation are joined—took over the magnesite-mining operations of the Barium Products Co., Ltd., in supplying magnesite to its parent companies. Relatively minor amounts of magnesite were furnished to the California plants of the Westvaco Chlorine Products Corporation from the East Ely mine in eastern Nevada.

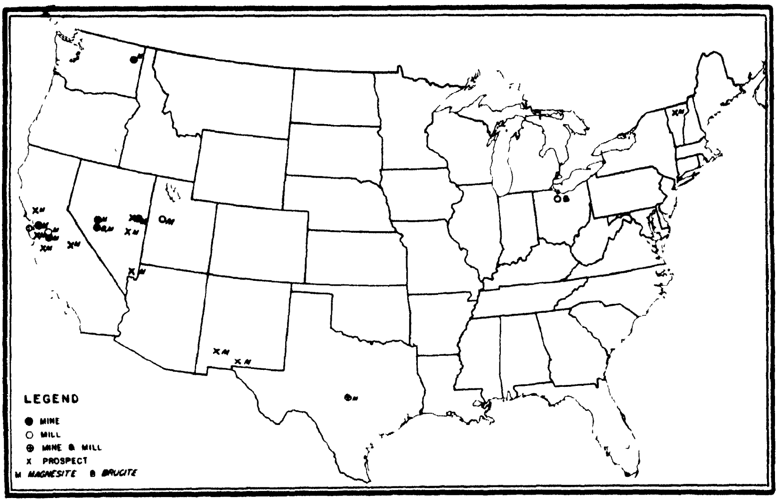

FIGURE 1.—Geographic distribution of magnesite and brucite mines, mills, and prospects in the United States.

The production of magnesite in Nevada increased greatly during 1941. In addition to the large shipments made by the Sierra Magnesite Co. to the magnesium-metal-producing plant of the Permanente Corporation and to the calcining and processing plants of the Westvaco Chlorine Products Corporation, substantially increased production of magnesite and brucite was reported by Basic Ores, Inc., subsidiary of Basic Refractories, Inc. (454 Hanna Bldg., Cleveland, Ohio), during 1941. Basic Magnesium, Inc., also a subsidiary of Basic Refractories, Inc., was organized during the year and has started construction of a $3,000,000 plant designed to produce and process 2,000 tons of magnesite a day; this plant will include crushing, grinding, flotation, and calcining units and is expected to be completed by December 1942. Products from this area must be trucked 32 miles to Luning, Nev., nearest rail shipping point. Magnesia produced by Basic Magnesium, Inc., will be sent to Las Vegas, Nev., to be converted into magnesium metal.

In a paper read before the Industrial Minerals Division of the American Institute of Mining and Metallurgical Engineers at Rolla, Mo., October 1941, Max Y. Seaton discussed the magnesite holdings near Luning, Nev.:

As there has been a considerable amount of confusion in published statements with reference to holdings in the district, it may be well to briefly clarify them. The oldest interests are those of the U. S. Brucite Co., whose property apparently

contains the principal deposit of brucite, together with large tonnages of magnesite. This property is leased to Basic Ores, Inc., a subsidiary of Basic Refractories, Inc., of Cleveland. Under this lease, U. S. Brucite retains the rights to magnesium-containing materials used for other than refractory purposes. In addition to Basic Ores' leasehold of the property mentioned, it holds, as mineral claims or as patented mineral land, a substantially larger area than that comprising U. S. Brucite's holdings. Much of this land contains showings of magnesite, and certain proportions of it are under active development at the present time. The third holder of property in the district is the Nevada Massachusetts Co. (including the interests of Charles Segerstrom and Frederick Thornton). The so-called Segerstrom property, a relatively small but extremely rich area, is a section originally prospected for tungsten and is under lease to the Sierra Magnesite Co., which is a corporation in which the interests of Henry J. Kaiser and his associates and Westvaco Chlorine Products Corporation are joined. The Sierra Magnesite Co.'s operations are directed toward supplying both the needs of Kaiser and Westvaco for magnesite ore. The fourth holder of properties near Luning is the Standard Slag Co. of Youngstown. Its property is substantially smaller than the U. S. Brucite's holdings but probably contains at least some brucite in addition to much medium-grade magnesite. In the condensed description above, some general idea as to the areas of the various holdings has been suggested; relatively exact knowledge as to ore reserves exists only with reference to the brucite on the U. S. Brucite Corporation's claims and with reference to magnesite on a small portion of the Segerstrom property. Data are not yet available to indicate the relative tonnages of usable ore likely to occur in the four properties in this district.

Two companies reported production of magnesite from the Llano district of Texas and one from Juab County, Utah, during 1941. Consideration has been given to the production of refractory magnesia from a high-grade magnesite deposit in the Burro Mountains about 35 miles northeast of Lordsburg in southwestern New Mexico. The deposit is reported to consist of three veins, each 14 feet wide and 1,500 feet on the strike. A typical analysis of the crude magnesite indicates the presence of 41.31 percent MgO, 1.55 percent CaO, 1.07 percent SiO_2, 0.32 percent Fe_2O_3, 0.43 percent Al_2O_3, and 55.32 percent ignition loss. A corresponding analysis of the calcined material indicates 92.46 percent MgO, 3.47 percent CaO, 2.39 percent SiO_2, 0.72 percent Fe_2O_3, and 0.96 percent Al_2O_3.

In the Federal District Court for the Southern District of New York, on July 22, 1941, four corporations and seven individuals were assessed fines totaling $76,500 for violation of the antitrust laws in the production and sale of magnesite and magnesite brick. The indictment returned on January 20, 1941, charged the Harbison-Walker Refractories Co., General Refractories Co., American-Austrian Magnesite Corporation, and Austrian Magnesite Co., Ltd., with entering into contracts with a group of foreign companies whereby the world markets were so divided as to give each group exclusive territories without competition.

Several proposals for the recovery of Canadian magnesite were given serious consideration during 1941. The British Columbia Magnesium Co. was organized and has done considerable exploratory work on several hydromagnesite deposits in the Williams Lake district and in the Clinton district of British Columbia. The concentration of magnesitic dolomite from Kilmar, Quebec, by flotation processes was studied by the Canadian Department of Mines and Resources.[8] Magnesite recoveries of 50 to 60 percent, having a lime content of 2.0 to 4.5 percent, depending on the nature of the feed, were obtained

[8] Canadian Mining Journal, The Concentration of Magnesitic Dolomite from Kilmar, Quebec, Magnesite Recoveries Bears Relation to Lime Content of Native Rock: Vol. 63, No. 3, March 1942, pp. 157–165.

from feeds containing 13 percent lime and 46 percent magnesite. The reagents used were soda ash, quebracho extract, oleic acid, and American Cyanamid frother No. 60. A brief review of the Canadian resources of magnesite, as well as other sources of magnesia including brucite, dolomite, magnesitic dolomite, magnesium silicates, brines, and salines is given in a recent article by Goudge.[4]

Owing to the cessation of imports from Axis-controlled countries, considerable interest was attached to the development of sources of magnesite in Latin America. Two large deposits of satisfactory-grade magnesite occur near Brumado in the southwestern part of the State of Baía, Brazil. Adequate transportation facilities are, however, lacking, and several years would be required for large-scale production to be realized. Perhaps of more interest is the discovery of high-grade magnesite in northeastern Honduras. This deposit, reported to be large, is fairly accessible to the railroad. The importation of crude magnesite from Santa Margarita Island off the west coast of Lower California, Mexico, to be calcined at Chula Vista, Calif., has been proposed. The present duty of $9.375 per short ton on imported crude magnesite, however, makes such an operation uneconomical. A relatively large deposit of good-grade magnesite near Gatooma, Southern Rhodesia, has likewise been suggested as a source of magnesite for export both to the United States and to England. The critical lack of available shipping facilities, however, makes this, as well as magnesite deposits in Latin America, of doubtful value at present.

The maximum price of the maintenance grade of domestic grain magnesite in bulk, f. o. b. Chewelah, Wash., was established at $22 a ton on January 28, 1942, by the Office of Price Administration. For carlots of the product, in bags or sacks, the price established was $4 above the ceiling price for magnesite sold in bulk. The maximum price established by the schedule was that which had prevailed for the previous 3 years. On March 6, 1942, however, some sales of dead-burned grain magnesite at a maximum of $32 per ton f. o. b. California shipping points were permitted to cover high-cost production necessitated by the great wartime demand for refractory magnesite. Although only maintenance grades of dead-burned magnesite were covered by the price limitation, maximum price schedules were planned for other grades of magnesite and basic refractories. Prices of the chemical grade of domestic caustic calcined magnesite in bags, f. o. b. New York, N. Y., in less than carlots started a gradual increase in April 1941 and rose from $65 to $70 per ton to $83 to $88 per ton in April 1942, according to price quotations listed in the Oil, Paint and Drug Reporter. The corresponding price f. o. b. mines in California in April 1942 was $58.75 per ton.

REFRACTORY MAGNESIA FROM SOURCES OTHER THAN MAGNESITE

Sources of magnesia other than magnesite have gained importance rapidly. Almost 33 percent of the refractory magnesia produced in the United States during 1941 originated from these sources. Production of brucite by Basic Ores, Inc., from the Luning district of Nevada, only commercial source of brucite in the United States, reached a

[4] Goudge, M. F., Sources of Magnesia and Magnesium in Canada: Trans. Canadian Inst. Min. and Met., vol. 45, 1942, pp. 191-207

new high; the ore was shipped largely to the Maple Grove plant of Basic Refractories, Inc., of Cleveland, Ohio, to be combined with dolomite, iron oxide, and silica or silicates for the manufacture of a stabilized dolomitic refractory. The Aluminum Co. of Canada, Ltd., started to construct a plant at Wakefield, Quebec, for the recovery of magnesia from the extensive brucite deposits in the Gatineau River Valley some 14 miles northwest of Hull, Gatineau County, Quebec. The process to be used has been developed by the Canadian Department of Mines and Resources during the last 3 years. Other large deposits of brucite have been found in and around BrysonTownship, Quebec, and in the vicinity of Rutherglen, Ontario. Consideration has been given to the plan to use brucite from these deposits for the manufacture of magnesium metal as well as of basic refractories.

Other sources of magnesia also were actively exploited during 1941. The Newark (Calif.) plant of the Westvaco Chlorine Products Corporation operated at capacity, preparing high-grade magnesia products from sea-water bitterns obtained from salt plants in the vicinity of San Francisco. Recent improvements in the plant have been described.[5] An important plant to be operated on sea-water bitterns is being constructed by the West Indies Sales Co. in the Bahama Islands to supplement domestic production of much-needed high-grade refractory magnesia.

Owing to the high purity of the magnesia required for magnesium-metal production, considerable quantities of the raw material required for this purpose have been supplied from the Newark sea-water product in an exchange agreement between the Permanente Corporation and the Westvaco Chlorine Products Corporation. Moreover, at least one plant to produce additional magnesia from raw sea water and dolomite is being constructed on the California coast.

Late in 1941 the Northwest Magnesite Co. announced plans for the construction, at Cape May, N. J., of a refractory magnesia plant which is to use dolomite (shipped from near Philadelphia) and raw sea water as sources of magnesia. This plant is designed to produce about 40,000 tons of refractory magnesia a year, but provisions have been made for the addition of more units. Priorities have been granted for the materials used in its construction, which is being financed entirely by the Northwest Magnesite Co., and it is expected to be completed during July 1942. In the process to be used here and at the plants on the California coast, the calcium hydroxide of milk of dolomite is used to precipitate magnesium hydroxide from the magnesium chloride in sea water. The precipitated magnesium hydroxide and the unreacted magnesium hydroxide from the milk of dolomite are settled, filtered, and calcined to yield the desired products. This magnesia contains as impurities small quantities of lime that do not react completely with the magnesium chloride or are carbonated by the atmosphere, all the siliceous impurities in the milk of dolomite, and quantities of reagents (such as iron oxide) added for their modifying effects in processing. Developments similar to these are occurring throughout the world.

Recovery of magnesia from natural brines is also increasing. The Michigan Chemical Co. is constructing a plant at Saint Louis, Mich.,

[5] Pit and Quarry, Sea-Water Magnesite Plant Improved: Vol. 33, No. 10, 1941, pp. 45, 47.

which is expected to yield 15,000 tons of refractory magnesia from dolomite and from natural brines in that area. Completion of this plant is expected during the latter half of 1942. It is reported that refractory magnesia is to be recovered from the magnesium content of the brines of Great Salt Lake in Utah. The salt content of the lake ranges from 14 to almost 28 percent, depending on the level of the lake, and is composed of 55.5 percent chloride ions, 6.6 percent sulfate ions, 33.4 percent sodium ions, 1.9 percent potassium ions, 2.3 percent magnesium ions, and 0.3 percent calcium ions. Precipitated gypsum undoubtedly would be a byproduct of the operation.

Increased production of magnesia from dolomite was recorded during 1941. The Standard Lime & Stone Co. of Baltimore, Md., operated its process at capacity during the year, leaching calcium hydroxide from milk of dolomite to produce a high-MgO product for refractory use. The Diamond Alkali Co., in cooperation with Basic Refractories, Inc., is reported to have produced a limited quantity of magnesia from calcined dolomite by treating this material in its ammonia stills. The bulk of the magnesia so recovered was said to have been shipped to the Maple Grove (Ohio) plant of Basic Refractories, Inc., for conversion to refractory products. The Diamond Alkali Co. will utilize this operation as part of its process for the manufacture of magnesium metal.

Basic Refractories, Inc., continued to manufacture its stabilized dolomitic refractory from dolomite, brucite, silica or magnesium silicates, iron oxide, and other components. Although this product contains only 65 percent magnesia, it competes directly with dead-burned magnesite for many uses and may therefore be considered in this discussion of refractory magnesias from sources other than magnesite.

The Warner Co. of Philadelphia, Pa., continued work in the pilot plant on methods of recovering magnesia from dolomite by dissolving the calcium content as calcium bisulfide with hydrogen sulfide. Owing to the urgent need for high-grade refractory magnesia, a large commercial plant to use this process is being constructed. MacIntire,[6] working for the American Lead, Zinc & Smelting Co., patented a process for recovering magnesia from dolomite. His process involves treating half-burned dolomite with water and hydrogen sulfide to form a solution of magnesium bisulfide. The calcium carbonate is removed, and magnesium hydroxide and hydrogen sulfide are recovered by boiling the solution. Stump [7] patented a method of differentially carbonating a milk of dolomite in such a way that only the $Ca(OH)_2$ is carbonated, whereas the $Mg(OH)_2$ is left unaffected. The calcium carbonate and magnesium hydroxide are separated by mechanical means.

The possibility of using magnesium silicates in the manufacture of magnesia attracted increasing attention during 1941. Olivine has been used for several years in the manufacture of Epsom salts on a small scale, and much experimentation has indicated the feasibility of using olivine and serpentine in the manufacture of magnesium metal. H. R. Brandenburg [8] has patented a process for obtaining

[6] MacIntire, W. H., Magnesium Oxide from Dolomitic Rock: U. S. Patent 2,118,353, May 24, 1938.
[7] Stump, Horace, E., Carbonating Lime and Separating it from Magnesia: U. S. Patent 2,231,965, February 18, 1941.
[8] Brandenburg, H. R., Magnesium Oxide Recovery from Serpentine: U. S. Patent 2, 210,892, August 6, 1940.

magnesia from serpentine. In this process, serpentine calcined at about 700° C. is leached with water and carbon dioxide to form magnesium bicarbonate. Magnesia is obtained by calcining the precipitated basic magnesium carbonate resulting from heating the solution of magnesium bicarbonate. About one-third of the magnesium in serpentine may be recovered in this manner.

DOLOMITE

Responding to the demands of the steel industry, sales of dead-burned dolomite by domestic producers advanced 23 percent over the 1940 level to a new high of 1,069,887 short tons. Most refractory dolomite plants were operated at or near capacity, and increased production facilities seemed to be needed in some places. As in 1940, no imports of dead-burned dolomite into the United States were reported. The year 1941 was marked by an increased use of dolomite as a source of magnesia. As noted in the preceding section on Refractory Magnesia from Sources Other than Magnesite, two companies utilized dolomite for the manufacture of refractory magnesia, and several more were constructing plants or studying processes for that purpose. However, the various magnesium-metal plants now under construction probably will consume far more calcined dolomite than those in which refractory magnesias are or will be produced.

Dead-burned dolomite sold in and imported into the United States, 1937–41

Year	Sales		Imports [1]		Year	Sales		Imports [1]	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1937	617,706	$5,217,833	9,083	$231,084	1940	867,909	$6,925,328		
1938	366,626	3,095,355	2,875	67,340	1941	1,069,887	9,111,172		
1939	671,561	5,447,554	186	4,260					

[1] Reported as "dead-burned basic refractory material."

Nine plants that will use dolomite in the production of magnesium are now under construction. The processes to be used are described in some detail in the Magnesium chapter of this volume. Estimates place the total calcined dolomite to be used in the war program for production of magnesium metal at nearly 600,000 tons annually. Important as this quantity may be, however, it is less than that used for refractory purposes in normal peace times.

An interesting information circular on dolomite was published by the Bureau of Mines.[9] This paper discusses most of the uses of dolomite in some detail and also indicates the location of the principal deposits from which dolomite has been recovered. Another information circular dealing more particularly with the uses of dolomite in the chemical and processing industries was also published by the Bureau of Mines during 1941.[10]

OTHER MAGNESIUM COMPOUNDS

Production of magnesium compounds (other than magnesias similar to caustic calcined or dead-burned magnesite) from natural brines, bitterns, or saline deposits continued to expand and reached a new high level of 137,357 tons valued at $3,587,784 in 1941, a 27-percent increase in quantity over the previous high of 108,266 tons valued at $2,452,814 in 1940. The huge war demand for magnesium metal spurred the production of magnesium chloride and increased its lead over other magnesium compounds still further. Almost two-thirds of the projected 362,500 tons of annual magnesium-producing capacity for the war program will utilize electrolysis of magnesium chloride. Adding other consumption of magnesium chloride to that for magnesium metal, the total will approach a million tons annually, which is many times the 1940 total. To produce the great tonnages of magnesium chloride required, operations of the Dow Chemical Co. at Midland, Mich., and at Freeport, Tex., and of the Westvaco Chlorine Products Corporation at Chula Vista, Calif., were maintained at capacity during the year.

Magnesium compounds imported for consumption in the United States, 1937–41

The Bureau of Mines is conducting exploratory work to determine the feasibility of a plant to produce magnesium chloride from saline deposits at depths ranging from 2,200 to 4,200 feet near Thompsons, 30 miles north of Moab, Grand County, Utah. The brines are said to contain almost 32 percent solids that consist approximately of 52 percent magnesium chloride, 27 percent calcium chloride, 13 percent potassium chloride, and 8 percent sodium chloride; about 0.15 to 0.20 percent of bromine is also present. The erection of a plant capable of producing 500 tons of anhydrous magnesium chloride daily has been proposed. Bromine and potassium chloride also would be recovered.

Recently a large deposit of brine about three times as rich in magnesium salts as that used by the Dow Chemical Co. at its Midland (Mich.) plant has been discovered near Ludington, Mich. It is planned to use magnesium chloride extracted from this brine for the annual production of 72,000 tons of magnesium metal, most of which will be manufactured by the Dow Chemical Co.

The magnesium chloride obtained as a byproduct of the production of potassium sulfate by the Union Potash & Chemical Co., Carlsbad, N. Mex., subsidiary of the International Minerals & Chemical Co., is also to be used as a source of magnesium metal. Anhydrous magnesium chloride will be shipped to Austin, Tex., for conversion into metal. Additional metal will be produced at this plant from dolomite as raw material.

Production of magnesium chloride from other sources, notably dolomite and magnesium silicates, is expanding rapidly. Of the huge quantity of magnesium chloride needed for magnesium-metal production, over 200,000 tons will be derived from dolomite and additional quantities may be obtained from olivine and serpentine. The chapter on Magnesium in this volume contains further details concerning these developments.

Production of magnesium sulfate from natural brines increased substantially during 1941. Production was reported in Michigan, Texas, and Washington, with one plant in each State. The recovery of Epsom salts from Epso Lake in north central Washington by the C. A. Kearney Co. of Tonasket, Wash., has been discussed in Mining World, July 1941 (pp. 29–31).

Naturally occurring brines rich in magnesium sulfate found west of the Pecos River in Eddy County, southeastern New Mexico, were described by Lang.[11] These brines average 382 grams per liter solids content, of which 44 percent is magnesium sulfate, 39 percent sodium sulfate, 10 percent magnesium chloride, 4 percent potassium sulfate, 2 percent magnesium borate, and 1 percent magnesium carbonate. Interest was expressed in utilization of these brines as a source of raw material for magnesium-metal production.

Considerable expansion of the magnesium sulfate plant near Sylva, N. C., is contemplated, although no action was taken during 1941. This plant produces Epsom salts by the digestion of olivine with sulfuric acid, followed by leaching, purification, and crystallization of the magnesium sulfate so produced.

Methods for preparing magnesium sulfate by treatment of magnesium hydroxide and gypsum with CO_2 [12] and by calcination of a mixture of serpentine and iron pyrites [13] have been described. The first of these methods is carried out in an aqueous medium always containing some magnesium hydroxide rather than in a solution saturated with carbon dioxide. In the other method, only about one-third of the magnesium present in the serpentine may be recovered as magnesium sulfate.

A strong plaster, described by Cunningham,[14] has been prepared by heating gypsum in 30- to 35-percent magnesium sulfate solution at 265° F. for about 45 minutes. The calcium sulfate hemihydrate resulting from heat treatment of the gypsum is filtered from the Epsom salts solution and is washed, dried, and ground in a ball mill to produce a plaster holding 33 to 45 cc. of water per 100 grams and having a tensile strength when set of 490 pounds per square inch and a compressive strength of 4,610 pounds per square inch.

A series of British patents [15] on a new process for the recovery of magnesium compounds from sea water has been issued. The process involves precipitation of magnesium hydroxide from sea water in the usual manner, followed by dissolution of this precipitate with carbon dioxide under pressure. The resulting solution of magnesium bicarbonate is passed through a column of an organic cation-exchange material saturated with a sodium compound. This results in the formation of a solution of sodium bicarbonate from which sodium carbonate may be recovered. Magnesium chloride may be obtained by passing raw or treated sea water through the column saturated with magnesium ions. Magnesium sulfate may be obtained by treating the magnesium-saturated cation-exchange material with sulfuric acid followed by neutralization. Patents on pretreatment of sea water and on the precipitation of magnesium hydroxide and magnesium silicate are included in this series.

Prices of most magnesium compounds remained constant during 1941. Anhydrous magnesium chloride sold at 13 cents per pound delivered in barrels, while the price of flake magnesium chloride packed in barrels remained at $32.00 per ton, f. o. b. works. Technical Epsom salts sold at $1.80 per 100 pounds in bags. No changes in price occurred among the more usual grades of magnesium carbonate, oxide, or hydroxide.

A new magnesium mineral, bradleyite ($Na_3PO_4.MgCO_3$), was reported by Fahey and Tunell.[16] This mineral occurs as a 1-inch layer at a depth of 1,343 feet in the drill core in which the mineral shortite was found in Sweetwater County, Wyo.

CALCIUM CHLORIDE

Sales of calcium chloride and mixed calcium-magnesium chloride obtained from natural brines totaled 165,932 short tons in 1941, basis 75 percent (Ca, Mg) Cl_2, a 67-percent increase over the 1940 total, resulting largely from increased business activity noted generally throughout the Nation. Exports of calcium chloride in the first 9 months of 1941 were 15,961 short tons, or almost double the total for 1940. Customarily exports of calcium chloride, although having a wide distribution, go largely to Canada, Argentina, Venezuela, Cuba, Netherlands Indies, and Mexico.

1938	96,470	1,218,938	1941	165,932	1,333,370
1939	108,441	1,307,717			

[1] Revised figures

Calcium chloride imported for consumption in and exported from the United States, 1937–41

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1937	2,205	$24,908	21,731	$415,309
1938	1,642	21,174	24,118	396,981
1939	996	12,314	19,382	318,199
1940			8,907	194,738
1941 (January-September)	7	795	15,961	376,912

Calcium chloride is consumed chiefly in road stabilization, surface consolidation, and dust laying; other uses are for highway ice control, dust-proofing coke and coal, refrigeration, concrete acceleration and conditioning, manufacture of chemicals, and air conditioning. Substantially increased consumption for concrete acceleration and conditioning during 1941 resulted primarily from increased construction of defense projects. It is expected that the use of calcium chloride in dust- and freeze-proofing coal and dust-proofing coke will increase if oil-transportation difficulties cause increased utilization of coal for domestic heating purposes.

A new use for calcium chloride, and one that will doubtless become very important in the near future, is in conjunction with dolomite in the manufacture of magnesium metal by processes to be used by several alkali companies. It is estimated that the production of magnesium metal alone will consume about 300,000 tons of the equivalent of 75-percent calcium chloride annually before 1943.

Calcium chloride prices tended to decrease during 1941. Prices of flake calcium chloride of 77- to 80-percent concentration, which at the beginning of the year were quoted by the Oil, Paint and Drug Reporter at $20.50 to $35.00 per ton in carlots of material packed in drums, by the middle of June were quoted for material in paper bags because of increased package costs. Prices for calcium chloride in drums were $3.50 per ton more and those for calcium chloride in burlap bags $2.50 per ton more than for material in paper bags. Early in November the prices of calcium chloride in paper bags were reduced to the range of $18.50 to $35.00 per ton.

BROMINE

Production of bromine continued its phenomenal rise which began in 1926 by advancing 15 percent from its 1940 level to 34,159 short tons in 1941. The high pitch of business activity, involving increased consumption of gasoline of ever-improving antiknock rating, has been

chiefly responsible for this increase, although the expanding miscellaneous uses for bromine compounds have also played important roles. During 1941 bromine was produced in 14 plants distributed throughout the Nation, as follows: Michigan, 5; Ohio, 1; West Virginia, 4; California, 2; and North Carolina and Texas, 1 each.

The Ethyl-Dow plant at Freeport, Tex., was a very important new domestic producer of bromine, having gone into production in March 1941; it operates in conjunction with the Dow plant that produces magnesium metal at the same location. The bromine from the plant appears largely in the form of ethylene dibromide, a compound produced from the recovered bromine and the natural gas piped to the plant. The addition of this new plant to the Ethyl-Dow bromine-production facilities increases still further the already great fraction of the total domestic bromine production controlled by the company.

Bromine and bromine in compounds sold or used by producers in the United States, 1937-41

Year	Pounds	Value	Year	Pounds	Value
1937	26,200,256	$5,180,177	1940	59,266,275	$11,772,515
1938	33,324,116	6,610,056	1941	68,317,019	11,506,213
1939	37,882,005	7,611,400			

The process used by the American Potash & Chemical Corporation, another relatively new producer in the field, for recovering bromine is described in a recent patent.[17] It involves concentrating the raw brine from Searles Lake substantially to saturation with respect to potassium chloride and then cooling the liquor to separate mixed crystals of potassium chloride and of potassium bromide, which is isomorphous with it. Concentrations of potassium bromide as high as 1.8 percent of the crystalline product are obtained. These crystals are separated from the mother liquor and dissolved, and the solution is treated with chlorine to release the bromine, which is recovered by steam distillation. Pure potassium chloride is crystallized from the debrominated solution. Bromides will be prepared from bromine by a recent modification of the van der Meulen process,[18] in which bromine is reacted with a metal hydroxide or carbonate in the presence of an easily reduced material, yielding only water and gases as products of reduction.

By far the greatest part of the bromine manufactured in this country is used as ethylene dibromide in the preparation of ethyl fluid, which is added to gasolines to improve their antiknock qualities. Other important uses for bromine compounds are in photography, medicine, fumigation, and chemical synthesis. Although not yet used to an appreciable extent in World War II, many war gases and lachrymators contain bromine and consumed a very appreciable tonnage of bromine during World War I. Germany is reported to have large stores of poison gases on hand, and it is probable that other warring nations likewise are producing such weapons in appreciable quantities. Should

[17] Gale, Wm. A., and Pearson, E. P., Recovery of Bromine and Iodine from Brines Such as Searles Lake Brine: U. S. Patent 2,251,353, August 5, 1941.

[18] Meulen, J. H. van der, Alkali or Alkaline Earth Metal Bromides: U. S. Patent 1,775,598, September 9, 1930.

poison-gas warfare become active, large quantities of bromine doubtless would be necessary for the manufacture of the requisite gases and other chemical agents.

Some progress has been made in the problem of shipping elementary bromine. Under present practice, bromine is shipped in cases of nine glass bottles, each containing 6.5 pounds of bromine. The net weight of this unit is 58.5 pounds of bromine, and the gross weight is about 140 pounds. A recent German patent (No. 694,408) suggests packaging the bromine in light sheet-iron containers coated with lead and partly filled with tetramethyl-ammonium bromide. Bromine is added to this compound in the container to form a solid molecular compound, of which 93 percent is bromine. The containers are equipped with openings, and the bromine is introduced through tubes. When it is desired to remove the bromine, hot air or steam is injected, and at 40° C. the bromine melts and can be withdrawn, leaving the tetramethyl-ammonium bromide, which can be used again. It is claimed that by this means the packing weight may be reduced to one-tenth of its former poundage.

Bromine prices remained constant during 1941, being quoted at 25 to 30 cents per pound for the purified material in 1,000-pound cases.

IODINE

Production of iodine in the United States again increased during 1941. Current figures may not be published, however, owing to the fact that only the Dow Chemical Co. and the Deepwater Chemical Co. reported production. The domestic output of iodine during 1937 (the latest year for which statistics have been published by the Bureau of Mines) was 299,286 pounds valued at $242,422. Imports of crude iodine amounted to somewhat over 339 short tons in the first 9 months of 1941; however, they are not a reliable index of consumption or activity in the iodine industry in a given year. This is due to the relatively limited use of this commodity and to the fact that the Chilean Nitrate & Iodine Sales Corporation, only iodine-importing organization, maintains large stocks in this country.

Crude iodine imported for consumption in the United States, 1937–41

Year	Pounds	Value	Year	Pounds	Value
1937	1,967,148	$1,784,491	1940	1,244,146	$1,296,181
1938	570,532	464,303	1941 (Jan.-Sept.)	678,865	769,272
1939	200,000	168,238			

Prices of crude iodine were the same at the end of 1941 as at the beginning. On June 16, 1941, the Chilean Nitrate & Iodine Sales Corporation raised the price of crude iodine from $1.35 per pound to $1.60, but when domestic producers failed to follow this advance the importers soon were forced to restore their quotation to its former level.

Iodine is used chiefly in pharmacy and photography, in table salt, and as a mineral supplement to animal feeds. Factors responsible for loss of iodine from iodized salt and iodized feeding stuffs have been studied by the Iodine Educational Bureau in collaboration with the Mellon Institute for Industrial Research. It was found that iodized

salt may lose as much as 40 percent of its iodine content during 18 months' storage, and iodized-mineral feeding mixtures may lose 9 to 20 percent in 4 months. This loss, however, has been overcome by milling 10 percent of the stearate of either calcium or magnesium with 300-mesh potassium iodide before mixing with the salt or feeding compound. This process, which is now in commercial application, is said to impart great stability to the iodide in the presence of salt or mineral oxidizing agents but to leave the iodide in a completely assimilable form.

SODIUM SULFATES AND CARBONATES

Production of natural sodium sulfate reversed its upward trend by decreasing 16 percent from the 1940 level to 157,524 short tons in 1941 owing partly to a 3½-month strike at the plant of one of the principal producers. It has been estimated[19] that the total 1941 consumption of salt cake was 525,000 to 550,000 tons, an increase of some 100,000 tons over the preceding year. Extended use of paper, especially for packaging, was largely responsible for this gain. Imports of sodium sulfate (almost all salt cake) during the first 9 months of 1941 were 61,508 short tons valued at $664,985, indicating an increased over-all rate of importation despite cessation of imports from Continental Europe.

Natural sodium sulfates and sodium carbonates sold or used by producers in the United States, 1935–41

Year	Sodium sulfates[1]		Sodium carbonates[2]	
	Short tons	Value	Short tons	Value
1935	38,706	$275,943	93,230	$1,173,003
1936	51,608	336,559	102,866	1,106,364
1937	80,053	599,[illegible]66	104,711	1,191,485

[2] Soda ash, bicarbonate, and trona.

Commercial shipments of sodium sulfate products from the plant of the Desert Chemical Co. of Dale Lake, Calif., were begun in September 1941. This plant recovers sodium sulfate and sodium chloride from a subterranean brine lake containing 22.5 percent NaCl and 7.5 percent Na_2SO_4. Fractional crystallization, dependent on natural variations in climatic conditions, is used to effect separation of the constituents of the brine.

The American Potash & Chemical Corporation, Trona, Calif., already leading producer of natural sodium sulfate products, will increase its annual productive capacity for salt cake by 50,000 tons during 1942. The entire production of the company was halted for almost 15 weeks (from March 15 until July 1, 1941) by a strike of plant workers. The process used by this company has been interestingly described by Robertson.[20] Use is made of the phase-rule rela-

[19] Oil, Paint and Drug Reporter, Salt Cake: Vol. 141, No. 5, February 3, 1942, p. 38.
[20] Robertson, G. Ross, Expansion of the Trona Enterprise: Ind. and Eng. Chem., Ind. ed., vol. 34, No. 2, February 1942, pp. 133–137.

tionships between solutions of sodium chloride and the other salts involved, whereby sodium sulfate and sodium carbonate are recovered from burkeite obtained as a byproduct in the recovery of potassium chloride and borax from the brines in Searles Lake, Calif.

The process used by the Ozark Chemical Co. at its Monahans (Tex.) plant to recover and dehydrate sodium sulfate has been described by Douglass and Anderson.[21] Glauber's salt is dehydrated at this plant by "submerged combustion." A somewhat similar process of evaporation of hydrous sodium sulfate has been described by Schultz and Lavine.[22] Their process of "interphase evaporation" by hot combustion gases from burning peat was suggested for the commercial development of the natural sodium sulfate of North Dakota.

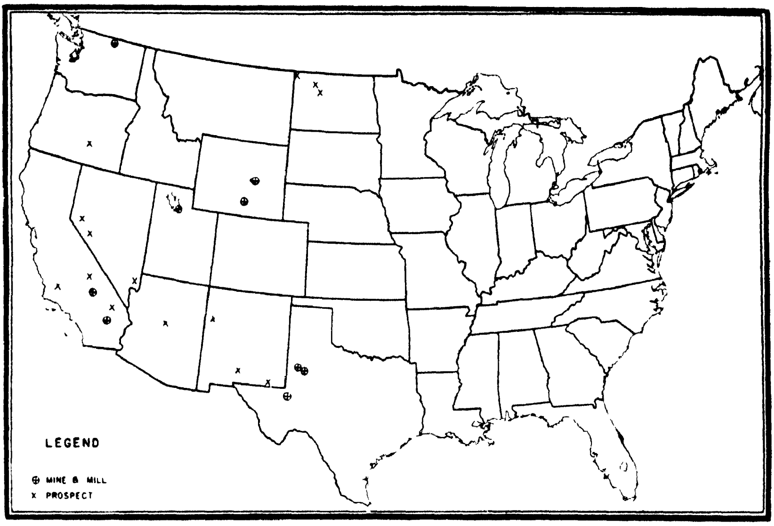

FIGURE 2.—Geographic distribution of sodium sulfate mines and prospects in the United States.

Several new sources of sodium sulfate have been discovered in New Mexico (see fig. 2). H. P. Powers of Gallup, N. Mex., reports discovery in that State of a large deposit containing over 80 percent sodium sulfate based upon the dry weight of the salts present. Minor constituents include magnesium sulfate and sodium chloride. The salts as recovered from the deposit contain some 45 percent moisture. The previously mentioned natural brines of southeastern New Mexico, described by Lang,[23] were also considered to be sources of sodium sulfate. It is suggested that sodium sulfate produced from this source could be sold to the nearby potash industry, to be used for converting sylvite into potassium sulfate and sodium chloride.

Prices of domestic salt cake in bulk were reduced to $13.00 per ton early in June 1941, despite the reduction in supplies brought about by the strike at the American Potash & Chemical Corporation. Prices, however, were increased to $15.00 per ton in September.

[21] Douglass, E. W., and Anderson, C. O., Submerged Combustion as Applied to Sodium Sulfate Production. Chem. and Met. Eng., vol. 48, No. 5, May 1941, pp. 135–137.
[22] Schultz, Robert F., and Lavine, Irvin, Interphase Evaporation of Sodium Sulfate Solutions: Ind. and Eng. Chem., ind. ed., vol. 34, No. 1, January 1942, pp. 59–64.
[23] Lang, Walter B., Article cited in footnote 11.

Sales of natural sodium carbonates, all produced in California, increased 13 percent from the 1940 total to 146,677 short tons during 1941. Estimated[24] production of sodium carbonate by chemical means during 1941 was 3,512,000 short tons of ammonia-soda process sodium carbonate and 18,000 short tons of electrolytic sodium carbonate, indicating an increase of almost 16 percent over the 1940 total for chemically manufactured soda. Virtually all major consuming industries required more soda ash to cope with higher operating schedules. New munition plants and increased requirements of the aluminum industry because of vastly expanded production and utilization of lower-grade ores, however, were direct factors resulting from the great defense effort of 1941. Reduced consumption of sodium carbonate in the manufacture of plate glass (owing to the ban on manufacture of private automobiles) is likely to be more than offset by substitution of glass for other less available materials and by increases in glass-container manufacture resulting from efforts to conserve the supplies of tin. It has been suggested that the use of soda ash in the desulfurization of steel be greatly increased to save manganese. This use of soda ash is widely practiced in Europe. Estimated possible consumption of soda ash in this application is of the order of 35,000 tons.

To meet the expanded requirements for sodium carbonate, emphasis was placed on recovery from natural sources by rapidly constructed and relatively simple temporary plants rather than on large and costly soda-ammonia process plants. Because some of the temporary plants would operate on submarginal deposits, they would require higher prices for their products; but they could be dismantled after the emergency with little loss, whereas the larger ammonia-soda plants might create a relatively large overcapacity for a considerable period.

Pike[25] suggested the establishment of a huge chemical industry in Wyoming based upon large deposits of trona discovered in 1939 about 20 miles west of Green River. It is proposed to sink a shaft to the deposits, which lie at a depth of 1,500 to 1,600 feet. The estimated cost of producing the trona by using room-and-pillar mining methods is $1.50 per ton.

Prices of sodium carbonates remained constant during 1941, but a slight revision was made in contract prices for 1942 to cover the cost of burlap packings. The light and extra-light soda ash in carlots, in bags, ranges from $1.05 to $1.13 per 100 pounds and the dense, in bags, $1.15 per 100 pounds, according to the Oil, Paint and Drug Reporter.

The American Potash & Chemical Corporation of Trona, Calif., is making additions to its plant for recovering soda ash from burkeite, a byproduct of the recovery of potassium chloride and borax from the brines of Searles Lake. The additions are expected to make possible an increased output of 40,000 tons of soda ash annually.

BORATES

Domestic production of borates during 1941 reached 301,282 short tons, a 24-percent increase over 1940, despite the 3½-month strike

[24] Chemical and Metallurgical Engineering, Commodity Reviews, Alkalis, and Chlorine: Vol. 49, No. 2, February 1942, pp. 84–86.

[25] Pike, Robert D., Possibilities for a Wyoming Chemical Industry; Statement before the Subcommittee of Public Lands Committee of the United States Senate, July 23, 1941; Chem. and Met. Eng. vol. 48, No. 9, September 1941, pp. 112–113.

at the plant of one of the leading producers and a sharp decline in exports. Apparent consumption of borates is estimated to have reached an all-time high, greatly exceeding the previous high of 211,739 tons attained in 1936. Increased industrial activity, substitution of ceramic and enameled ware for metals and alloys needed for war purposes, and military needs were largely responsible for the expanded consumption.

[2] Also 348 pounds of crude valued at $7 in 1939.
[3] Figures cover January to September, inclusive.
[4] Quantity sold or used by producers plus imports minus exports.
[5] Figures not available for publication.

Owing to the strike at Trona, Calif., mentioned heretofore, a temporary but acute shortage of borates developed, and it became necessary for the Office of Production Management to place borax and boric acid under full priority control from June 9 until August 30, 1941, to assure adequate supplies for military requirements. Settlement of the strike, however, soon restored conditions to normal, and continuance of priority control became unnecessary after August 30.

Producers held prices of borates constant during 1941, although resale prices often were much higher during the strike period. Upon the basis of increased manufacturing costs, a price advance was allowed on January 28, 1942, by the Office of Price Administration, which undertook to review and determine prices at the request of producers. This advance amounted to $1.00 a ton over the figure of $40.50 per ton of granular borax, bulk, carlots, and $2.00 per ton for boric acid, the technical grade of which sold at $93.50 per ton.

Research on the production and uses of boron compounds was active during 1941. Their use as fertilizers for soils deficient in boron continued to engage scientists, and some progress was reported in this field. Powers,[26] in summarizing the biological effects of boron, says—

Boron appears to give elasticity to the plant cell membranes and to aid cell division. It seems to regulate respiration, lessen effect of drought, has improved keeping qualities of apples and prunes, and prevents swelling and blocking of roots and pollen tubes. Boron prevents break-down of conduction tissues, is important in nitrogen metabolism, and aids development of nodules and nodule bacteria. Boron affects carbohydrate translocation and pectin formation and amount of calcium in tissues. Eaton (1940) reported boron to be essential to formation of auxin in plants, and Goldschmidt and Peters reported it essential in metabolism of brown algae. Boron is a constituent of animal tissues.

[26] Powers, W. L., Boron—A Minor Plant Nutrient of Major Importance: Better Crops with Plant Food, vol. 25, No. 6, 1941, pp. 9–11, 39–40.

The use of manganese or zinc borates together with chlorinated organic materials in fire-proofing compositions for textiles was begun during 1941. These borates, being fusible at low temperatures, cover the fibers on exposure to the flames. Thus, glowing and creeping of the fire are prevented; the chlorinated material alone could not do this. Zinc borate has the additional advantage of giving good resistance to mildew. A British patent [27] describes the use of boric acid esters as efficacious antioxidants for rubber and similar materials. Warth [28] reported tests indicating that borax has a rust-inhibitive action superior to that of any of the various alkaline reagents found in commerce and even to many so-called rust inhibitors. An Australian report indicated that boric acid was effective in the protection of timber against the powder post borers. Eight mills in Queensland and four in New South Wales are employing the new process, which has been in commercial use for approximately 2 years.

GEM STONES

By Sydney H. Ball

SUMMARY OUTLINE

JEWELRY INDUSTRY IN 1941

Retail sales by jewelry stores in the United States totaled about $526,000,000 in 1941, a 30-percent increase over 1940 (when sales totaled about $405,000,000) and within 2 percent of those in 1929. An additional 18 to 24 percent was sold by department stores.

Arkansas, Connecticut, and Indiana showed notable advances over 1940 in retail sales. Again, as in 1940, gains were due mainly to larger turn-over of relatively inexpensive items, and sales of high-priced articles were the exception. This can be explained, in New York at least, by the colorless stock market.

The jewelry trade had two "Christmases"—the first late in September, when taxwise buyers bought heavily to avoid the 10-percent excise tax, and the real Christmas. During both periods the buying rate was higher than at any corresponding time since 1929. Some expensive articles were sold during both buying seasons, and certain of these, strangely enough, were purchased by European refugees. In 1941 the gain in sales may have been in part a hedge against inflation, that is, investment buying; but furthermore, compared with 1940 the Nation's income had risen from about $72,000,000,000 to about $92,000,000,000. Sales were also increased by an all-time record number of marriages (1,565,000), over 16 percent above those in 1940, which had been the banner year.

From year to year in the larger cities, a few of the better department stores are cutting into sales of retail jewelers, and it may be added that, on the average, they are handling stock of finer grade year after year.

Wholesale jewelry sales in 1941 were somewhat greater even than those of the retailers, and stocks in retail jewelry shops increased 14 percent. Manufacturers' personnel was employed full time. During the year, exports to South America, which normally obtains its jewelry supplies from Germany, were large.

The national income of Canada is also rising ($5,180,000,000 in 1940—$6,200,000,000 in 1941), and retail jewelry sales in 1941 topped those of 1940. Canadian prices have as their ceiling those of the basic

period September 15–October 11, 1941. Luckily, the more important shops had fairly extensive stocks when the price order went into effect; but as the war progresses, the transfer of machinery and artisans to war work and the lack of certain materials may cause a shortage of articles, resulting in smaller retail sales.

FASHIONS IN JEWELS

Large, flamboyant jewelry characterized the mode in 1941, a year in which it was used even with sport clothes. Gold continued to be worn more than platinum, although the latter was used in the finer diamond mountings. For the first time, however, industrial consumption of platinum exceeded that of the jewelry trade. Regimental and other military insignia and the "V for Victory" pins and clips were popular, but floral decorations, grotesque animals, geometric designs, and Victorian and South American motifs were also seen. Ensembles set with similar stones and large jewelry pieces divisible into several ornaments continued in favor. Clips and lapel pins were especially popular; watches, bracelets, earrings, and necklaces were less so. Double wedding rings are gaining popularity.

The shortage of melee is decreasing the use of pavé mountings, and more and more fine gems are being set "sec." Stones, such as citrine and aquamarine, weighing up to 400 carats (over 2 ounces), were used in bracelets and pins. Diamond (including some brown stones for men), sapphire (largely blue, but also yellow and pink), and ruby were the most popular gems, followed by topaz, moonstone, emerald, aquamarine, and amethyst. Due to the insistent demand for diamonds, colorless stones were dominant, followed by blue, red, yellow, and green. For the first time in many years, yellow stones were more popular than green and were used almost as commonly as blue and red stones. Owing to wider knowledge of gem stones in the United States, some 40 varieties were used in jewelry in 1941, in contrast to the few kinds once worn.

DOMESTIC PRODUCTION

From the 1909 peak output of gem stones valued at $534,280, domestic production dwindled to only $3,000 in 1934; but since that year productior has increased progressively and markedly and in 1941 was valued at $240,000 to $770,000. The first figure is a rough estimate of the value of uncut stones used in jewelry and the second an estimate of the total value after cutting, including stones added to mineralogists' collections or sold to tourists, collectors, and rock gardeners. Of the total value, 70 percent represents members of the quartz family, 18 percent sapphires (largely used industrially), and 12 percent turquoise. The principal producing States (in approximate order of output) were Oregon, Montana, Washington, Nevada, Wyoming, and Colorado.

The interest in beautiful minerals continues to grow; the number of professional and amateur lapidaries is increasing, particularly in Oregon (largely Portland and Newport) and Washington. Dr. H. C. Dake says that in those States the shops are operating at capacity and there is a shortage of skilled labor; cabochon-cut gems are being sold to American makers of costume jewelry; and agate balance knives and

mortars and pestles are being produced. Local machine shops manufacture cutting equipment, including diamond saws.

Professional gem cutters operate also in New York, Rhode Island (Providence), Maine, North Carolina, Montana, and South Dakota. Gem cutting is carried on as a hobby in many States, notably in Idaho, Wyoming, Utah, and North Carolina. Owners of precious-stone claims complain that amateur mineralogists "high-grade" the deposits in the absence of a resident watchman.

Agate and jasper are collected in quantity in Oregon and Washington, particularly on the beaches of Lincoln County, Oreg. Most of this is cut by local lapidaries, although some rough is shipped to other States. Montana continues to produce a considerable quantity of fine moss agate from the gravels of Yellowstone River in the southeastern part of the State. Wyoming also furnishes good material. Alfred M. Buranek states that Utah produced about $10,000 worth of agate in 1941. Arthur L. Crawford describes the principal varieties as jasper from the east bank of the Colorado River in Grand County; agate from 6 miles east of Cisco, Grand County; and red jasper geodes from Tidwell, Emery County. Arkansas produces considerable rock crystal from the vicinity of Hot Springs. Farmers dig most of it in the winter, but mineral dealers also mine some. Most of it is sold to tourists as curios, but some is used in jewelry. Scott's Rose Quartz Co. produced considerable rose quartz from its mine near Custer, S. Dak., and sold some for jewelry use.

In 1941, Montana produced about 3,720 troy pounds of sapphire (of which perhaps 50 percent was first-grade material), valued at some $43,000. The principal producers are American Gem Mines at Philipsburg, owned by Charles H. Carp and J. S. and R. M. Kaiser, and the Perry-Schroeder Mining Co., dredge operator of Helena. The former company operates on the West Fork of Rock Creek in Granite County, and the latter obtains its stones as a byproduct of gold-dredging Missouri River bars in Lewis and Clark County. Most of the stones are sold for industrial use; if for any reason the supply of synthetic sapphire should be inadequate to satisfy war demands for instrument jewels, Montana sapphire would have prime importance. Carl J. Trauerman (Butte Daily Post, June 3, 1941) believes that, if necessary, Montana could produce 150,000 to 200,000 ounces yearly. Besides the two localities mentioned above, production could be obtained from Brown's Gulch in Silver Bow County, Dry Cottonwood Creek in Powell County, and lode mines of Yogo Gulch.

Turquoise ranks after the quartz family and sapphire in value of production, with a total of about $28,000. Nevada ranks first in output and Colorado second. The principal producer in Nevada was the Smith mine at Cortez, operated by A. Guisti, which produced over 7,550 pounds; the material is shipped to E. C. Smith, Santa Barbara, Calif. The King mine at Manassa, Colo., had an unusually successful year, as one "pocket" alone produced almost 700 pounds of good material. Richard M. Pearl reports that W. S. Kettering of Pueblo opened up a deposit in Pueblo County, Colo., in 1941, some of the product being good gem material. Imitation turquoise is cutting somewhat into western turquoise sales.

Further data furnished by B. F. Couch, Reno, Nev., suggests that Nevada alone produced turquoise worth at least $20,000 in 1940, so that the author's estimate of $20,000 as the country's production in

1940 (Gem Stones, p. 1401, Minerals Yearbook, Review of 1940) is probably somewhat low. The chief production centers are Royston and southern Death Valley (Nye County), Battle Mountain, Cortez, and Austin (Lander County), and one deposit in Mineral County. Couch says also that in 1941 Nevada produced over 2,175 pounds of good material worth $13,775, with two producers not reporting. The Smith mine in the Bullion district, Lander County, was the chief producer, followed by mines in northern Lander County and the Royston and Beatty districts, both in Nye County.

Richard M. Pearl (see Bibliography) states that Colorado has for several years ranked second among the States as a turquoise producer, the gem stone occurring at four localities in the southwestern part of the State. The principal mines are the Hall near Villagrove and the King near Manassa; both of these deposits occur in felsite porphyry. The deposit near Leadville occurs in Silver Plume (Algonkian) granite, and turquoise near Creede occurs as stream pebbles. The turquoise of the lode deposits is believed to have been deposited by cold meteoric waters in fractures and shear zones.

Alfred M. Buranek states that about $2,000 worth of variscite was produced from the Clay Canyon deposit near Fairview, Utah. Jewelers, museums, and mineral collectors were the purchasers.

Vergil E. Barnes (North American Tektites, University of Texas Publication 3945, Austin, June 1940, pp. 477–582) describes the only tektites yet found in North America. The first of these, which have been dubbed "bediastites," was found in Grimes County in 1936, and in all 482 have been recovered. To the local residents they are known as "black diamonds," and some have been cut for jewelry. They are found in an area 10 miles long and 5 miles wide. The tektites are black and have an average specific gravity of 2.37; the largest weighed 59.4 grams. Most of them are ellipsoidal, and a few are spherical or tabular with their exterior deeply furrowed. The tektites consist dominantly of silica (73.52 to 77.76 percent) and alumina (13.3 to 15.88 percent), with low lime. Barnes considers them fulgurites.

Several hundred carats of colorless and yellowish topaz was obtained from the Tarryall Mountains, Park County, Colo. Gems up to 5 carats in weight have been cut from this material (according to a letter from R. M. Pearl). Topaz Mountain in the Thomas Range, Juab County, Utah, also produced a little topaz. Dr. H. C. Dake reports that some nephrite of gem quality was obtained from the two Wyoming localities (Fremont County and 48 miles southwest of Lander); at the first locality the material is mined from a dike, and at the second it occurs as boulders. One mass weighed 119 pounds. He states that in 1941 about 1 ton of this variety of jade was produced, the best rough material selling for $5 a pound. Alfred M. Buranek states that a little fine pyrope garnet was mined near Mexican Hat in southeastern Utah. Some was sold to prominent jewelers. Only three or four Indians worked the catlinite deposit at Pipestone, Minn., in 1941.

Other gem stones produced in the United States in 1941 included agate (Arizona, Colorado, Georgia, Montana, Oregon, South Dakota, and Utah); agatized wood (Arizona (private lands surrounding Petrified Forest National Monument) and Wyoming); alabaster (South Dakota); amazonstone (central Colorado); amethyst (Colorado, Georgia, South Carolina, LaSal Mountains and San Rafael Swell in

Utah, and near Liberty, Wash.); apatite (South Dakota); aquamarine (Colorado, Georgia, North Carolina, South Dakota, and Wyoming); azurite (northern Colorado); carnelian (Bastrop and Colorado Counties, Tex.); chalcedony (Colorado); chrysoprase (North Carolina); emerald matrix (North Carolina); epidote (Milford, Utah); garnet (Georgia; rhodolite from Mason County, N. C.; and a variety from the Oregon coast known locally as "Oregon jade"); hematite (Platte County, Wyo.); jasper (Socorro County, N. Mex.); jet (Mesa County, Colo.); lapis lazuli (Gunnison County, Colo.); opal (Georgia and Wyoming); moonstone (North Carolina); opalized wood (central Washington); rhodonite (North Carolina); rock crystal (Colorado, Georgia, and Idaho); rose quartz (Maine and North Carolina); rutilated quartz (North Carolina); smoky quartz (Colorado, North Carolina, and Utah); sapphire and pink sapphire (Macon County, N. C.); and tourmaline (Milford, Utah).

A little pale emerald occurs in the beryl-bearing pegmatites northeast of Winnipeg, Manitoba, Canada.

IMPORTS

On January 2, 1942, the United States Department of Commerce announced that "in the interest of national and hemisphere war effort, no further detailed statistics concerning the foreign trade of the United States" would be published. Imports of precious and imitation stones (exclusive of industrial diamonds) into the United States for the first 9 months of 1941 totaled $22,802,940, a 19-percent decrease compared with the corresponding period of 1940. Details for 1941 are shown in the following table.

Precious and semiprecious stones (exclusive of industrial diamonds) imported for consumption in the United States in 1941 (January–September, inclusive) [1]

	Carats	Value
Diamonds:		
Rough or uncut (suitable for cutting into gem stones), duty free	124, 202	$5, 967, 938
Cut but unset, suitable for jewelry, dutiable	182, 652	13, 570, 481
Emeralds:		
Rough or uncut, free		
Cut but not set, dutiable	18, 497	247, 730
Pearls and parts, not strung or set, dutiable:		
Natural		145, 897
Cultured or cultivated		423, 918
Other precious and semiprecious stones:		
Rough or uncut, free		75, 111
Cut but not set, dutiable		2, 074, 363
Imitation, except opaque, dutiable:		
Not cut or faceted		9, 703
Cut or faceted:		
Synthetic		217, 988
Other		18, 806
Imitation, opaque, including imitation pearls, dutiable		26, 957
Marcasites, dutiable:		
Real [1]		22, 208
Imitation		1, 840
		22, 802, 940

[1] Figures for 1940 in Minerals Yearbook, Review of 1940, p. 1403, should read—Marcasites, real, $8,220; grand total, $37,769,135.

Imports of pearls and cut precious stones and imitation stones increased notably, while all other subdivisions decreased. Imports of uncut diamonds decreased sharply, suggesting that American cutters overbought in 1940. The decrease in cut imported was somewhat less drastic. The number of watch jewels imported in the first 9 months of 1941 totaled 79,875,751 valued at $1,769,689, compared with 98,771,042 valued at $1,831,007 in the 12 months of 1940.

Synthetic rubies and sapphires imported in the first 9 months of 1941 totaled 440,491 pieces worth $217,988, or 71.8 percent of the quantity and 75.3 percent of the value imported in the corresponding period of 1940. Imports of synthetics were small in the third quarter of 1941 and are believed to have been negligible in the fourth quarter.

GOVERNMENT REGULATIONS

Again, due to the war, Government regulations covering the jewelry trade were legion in 1941. Great Britain, Germany, Italy, and France made strong efforts to divert funds normally spent on jewelry to Government securities.

EFFECT OF WAR ON SOURCES OF GEMS

The prices of colored stones, like those for diamonds, have increased since the Second World War started. For instance, fine rubies and emeralds are 15 to 20 percent higher and some of the less noble gems and all synthetics even more.

War in the Pacific has removed Thailand and Indochina from the list of countries from which the United States obtains precious stones. The principal sources of zircons (rough, Indochina; cut in Thailand) therefore can no longer trade with us. Thailand also supplied a few sapphires and rubies. Japan provided most of our cultured pearls. Furthermore, as a result of the war, imports of gems from India will have to be rerouted, and receipt of precious stones from Burma may be temporarily interrupted.

With the declaration of war imports from Germany (largely imitation stones) and Italy ceased, and the difficulty of importing watches and watch parts—notably jewels—from Switzerland increased.

Bombay (Bureau of Mines Mineral Trade Notes, August 20, 1941, pp. 27–30) has long been one of the more important precious stone markets of the world. However, before the war started, Bombay had virtually no direct trade with the United States; its stones were exported to London or Paris—then the center of the trade in colored stones—where American gem merchants purchased their requirements. Bombay does not control the output of any important gem-stone deposits but has always been only a junction point in the world circulation of precious stones. However, conditions have changed since the war. In 1938 Bombay exported $35,169 worth of gem stones and pearls; in 1940, $443,020. The increase of its exports to the United States has been even more remarkable, because American importers now look to Bombay instead of Paris for their colored stones. The quantity of stones exported is controlled by the Reserve Bank of India. Rubies from Mogak, Burma, are the principal exports. Although star rubies are cut in Burma, other Burmese rubies are cut largely in Cambay, India, and a few in Bombay itself. The price of

rough rubies has increased 15 to 20 percent since the war began, although the price of cut stones has changed little. Star rubies and sapphires sell for four or five times their pre-war price. Sapphires are imported from Burma, Ceylon, and Kashmir and emeralds from Ceylon and U. S. S. R.; diamonds, formerly imported from Europe, usually are sold locally. Since March 1940, an export certificate, obtained at an accredited bank, is required before gems can be exported to the "hard-currency" countries. Precious stones cannot be imported from "hard-currency" countries. An ad valorem duty of 5 percent is paid on most stones imported, although gems from Burma are exempt from duty.

China is sending us tiger-eye and quartz cameos, which formerly were purchased in Germany.

Although there seems to be no deficiency in the supply of fine rubies, sapphires, and emeralds, there is a distinct shortage of the less expensive grades of these gems, of some of the lesser gems, and of synthetics. Brazil, however, is supplying the United States with sufficient aquamarine, topaz, citrine, amethyst, and tourmaline, and our imports (both cut and rough) from that country are increasing. In view of the unusually good demand for colored stones, the lack of adequate cutting facilities in the United States is unfortunate. American lapidaries are working overtime cutting South American rough and recutting into modern shapes stones recovered from old jewelry. Some South American chalcedony is being stained into black onyx

DIAMOND

A layman would have expected the diamond industry, which produces a luxury, to be one of the first adversely affected by the war. In reality, in 1941 it enjoyed relative prosperity, notwithstanding the fact that its processing branch—the cutting of gem stones—is about one-eighth as large as normally since the invasion of the Low Countries.

Production was appreciably smaller than in 1940 and, indeed, less than in any year since 1937. Sales of rough, on the other hand, were large, due partly to a slight increase in sales of gem stones in America but largely to huge sales of industrials. Prices of rough and fine large cut advanced; prices of small cut held at two to four times those of early 1940. "Investment" buying increased in 1941—in Europe in "black markets," in the United States in a free market.

Share dealings.—The shares of diamond-mining companies, virtually all of which are listed on the London Stock Exchange, gained over 75 percent during the year and in the fall were market leaders. Until Russia showed its strength, the market was uninteresting, but by mid-September a gain of 50 percent had been made. Prices sagged in October, rose sharply in November, weakened on the entrance of the United States (the chief market for cut) into the war, and at the year end strengthened on good dividend declarations. The market rise was in contradistinction to a 14-percent rise in English industrials and a loss of 18 percent during 1941 on the New York Stock Exchange. At the year end, diamond-mining stocks were 39 percent of their high (1927) and 445 percent of their low (1932). Of the 12 leading diamond-mining companies, 11 paid dividends; the twelfth, Cape Coast Exploration, is soon to make a handsome liquidation payment.

Market.—In 1941, the Diamond Trading Co., which in normal times controls the sale of about 95 percent of world production, sold

rough valued at about £7,500,000 (£6,144,314 in 1940). The United States bought such "American qualities" (fine, relatively large stones) as were available and some fine small rough, but the increase in sales was due principally to large purchases of industrial diamonds by the Governments of the United States and Russia and by American brokers. In addition to its London and Kimberley offices, the Diamond Trading Co. in the fall opened an office at Hamilton, Bermuda, to deal with cutters and brokers residing in the United States.

In 1941 the American market for cut was featured by an increasing demand, a reasonable supply of large cut, and a wholly inadequate supply of small cut. There was a fair turn-over in polished stones in Great Britain, notwithstanding Government attempts to restrict it. The finer stones were sold for "investment" purposes in a thriving "black market." South America, Canada, and India were relatively large buyers of cut. Citizens of Nazi-occupied Europe desired to "invest" in diamonds, but opportunities were few.

Prices of rough diamonds advanced 10 to 15 percent, and a further rise is likely early in 1942. Prices of fine, large cut are 10 to 20 percent higher than in pre-war days, and prices of small cut have doubled or quadrupled. In America, a fine 1-carat stone costs what it did before the 1929 crash; in Nazi-occupied lands and in the British "black market," prices are much higher.

Stocks of rough increased somewhat in 1941 but will decrease in 1942. Those in the hands of American cutters are adequate, as are those of fine, large cut; however, the supply of small cut is pitifully low.

Imports.—On September 30, 1941, the Department of Commerce ceased to publish import figures. Imports from January 1 to September 30, 1941, were as follows:

Diamonds imported into the United States in 1941 (January–September, inclusive), by countries

[Exclusive of industrial diamonds]

Country	Rough or uncut			Cut but unset		
	Carats	Value		Carats	Value	
		Total	Average		Total	Average
Argentina				146	$8,607	$58 95
Belgium				123,052	6,722,113	54 63
Brazil	35,825	$1,261,715	$35 22	2,470	276,702	112 03
British Malaya				73	6,872	94 14
Cuba				191	16,947	88 73
France				3,867	474,752	122 77
Germany				539	42,337	78.55
Mexico				432	35,314	81.75
Netherlands				1,123	42,384	37 74
Netherlands Indies				104	5,339	51 34
Palestine				3,409	398,123	116 79
Switzerland				630	108,796	172 69
Union of South Africa	88,377	4,706,223	53 25	31,043	3,776,182	121 64
U S S R				30	2,250	75 00
United Kingdom				15,543	1,653,763	106 40
	124,202	5,967,938	48 05	182,652	13,570,481	74 30

Cutting.—In May 1940 the world cutting industry was completely disorganized, having lost 90 percent of its operatives as a result of German invasion of the Low Countries. A few cutters escaped and

reestablished their trade in far corners of the earth, others were marooned in France, but most were caught in the Low Countries. The United States and South Africa and, to a smaller extent, Great Britain and Palestine furnish an adequate supply of "American qualities" (fine, large cut), but there is a woeful shortage of small cut. Germany has attempted without success to reestablish the industry in Belgium and the Netherlands.

By a fluke, New York is now the leading diamond-cutting center of the world, with some 650 cutters and a large number of apprentices. Several firms are attempting to cut melee. Some of the more experienced cutters make over $235 a week. South Africa has 300 to 400 cutters, Great Britain 200 to 250, Palestine perhaps 200, Puerto Rico 75, and Java a few. Borneo and Brazil cut some diamonds for the local trade, but their product is not cut well enough for the American market.

World production.—For the second year, due to the war, actual diamond-production figures are not available, but the estimates in the following table are believed to be fairly accurate. World production (gems and industrials) in 1941 is estimated to have been 9,088,000 carats (1.817 metric tons) valued at about $27,000,000. Compared with 1940, the total weight decreased 36 percent and the value 19 percent. The average quality of the stones produced was better than in 1940, bort representing perhaps 78 percent of the caratage and gem stones 22 percent. Belgian Congo was the leading world producer, both in weight (over 67 percent of the total) and in value (27 percent). The British Empire produced 19 percent of the total by weight and 31 percent by value. The South African pipe mines were not operated; consequently, all production was from alluvial mines.

The following table shows, as accurately as available statistics permit, world production for the past 5 years.

World production of diamonds, 1937–41, by countries, in metric carats

[Including industrial diamonds]

Country	1937	1938	1939	1940	1941
Africa:					
Angola	626,424	651,265	690,353	784,270	787,000

[1] Estimated

[2] Includes small quantity of diamonds derived from re-treatment of tailings.

[3] 1937: Includes Netherlands Indies (Borneo), India, Australia (New South Wales), Liberia, Venezuela, and Rhodesia. 1938: U. S. S. R., India, Borneo, New South Wales, and Venezuela; 1939: Venezuela, India, Borneo, New South Wales, and U. S. S. R.; 1940 and 1941: Borneo, India, New South Wales, U. S. S. R., and Venezuela.

Most countries showed decreased production as compared with 1940, although Sierra Leone and South-West Africa made minor increases.

During the year, DeBeers Consolidated Mines, Ltd., absorbed Cape Coast Exploration, Ltd., and now owns or controls all important diamond mines in the Union of South Africa and South-West Africa except the State mines of Namaqualand.

In 1942 some of the companies are to attempt to increase production of the industrial stones so necessary today and may succeed. If the war continues, however, the long-term outlook is for a drying up of production as certain essential supplies will be lacking owing to the isolated position of the mines now producing.

Industrial diamonds.—The use of industrial diamonds continues to increase amazingly. The expansion, of course, is due largely to the national defense and war programs, but even without a war the increase would have been marked. World consumption in 1942 is expected to approach 7,500,000 carats, or more than the world production of industrial grades. For several years, stocks of certain types of fine industrial diamonds have been small; however, users will find that the grades substituted are satisfactory.

With signing of the United States-Brazil Trade Agreement (May 15, 1941), the Axis Powers lost their last primary source of industrial diamonds. It is reported that Germany is now using gem stones industrially.

On March 18, 1941, industrial diamonds were classified among the critical war materials, and after April 15 they could not be exported from the United States without an affidavit, except to the British Empire. Since October 31, 1941, American dealers and users have had to report quarterly stocks on hand and transactions completed. The United States Government began to stock-pile diamonds in June 1940.

The percentages, by value, of the chief uses for industrial diamonds follow:

	Percent
Diamond drilling	45–40
Diamond-set tools	30–35
Diamond dies	10– 7
Crushing bort (bonded wheels and tools)	10– 7
Miscellaneous	5–11

In 1940, for the first time in 3 years, diamond drilling in Canada by contractors increased (1939: 391 miles; 1940: 459 miles). The use of diamond drills in stope blast-hole drilling also increased in Canada, and it is reported in the copper mines of Rhodesia and Belgian Congo. The use of diamond-impregnated bits in drilling is increasing.

The demand for diamond dies is large. Formerly the specialty of France, they are now being produced in America, and mechanical methods successfully replace meticulous hand methods.

The Diamond Trading Co. announced that it would not raise the price of industrial stones during the war Indeed, the price of Congo (Beceka) crushing bort was reduced in the summer of 1941. Whether the price differential between this grade and those of South Africa and Gold Coast is warranted seems questionable.

Imports of industrial diamonds into the United States during the past 5 years were as follows:

Industrial diamonds (glaziers', engravers', and miners') imported into the United States, 1937–41

Year	Carats	Value		Year	Carats	Value	
		Total	Average			Total	Average
1937	1,885,970	$6,542,365	$3.47	1940	3,809,071	$11,026,563	$2.89
1938	1,396,247	4,213,412	3.02	1941 (Jan.–Sept.)	2,911,117	7,415,133	2.55
1939	3,568,730	9,725,683	2.73				

RUBY, SAPPHIRE, AND EMERALD

Production of precious stones in Burma seems fairly well stabilized. The 1939 production was 211,570 carats of rubies and 10,532 carats of sapphires. A few spinels and other gem stones are byproducts.

Sapphires continued to be produced in 1941 in the Anakie field, Central Queensland. Prices reached perhaps an all-time peak; £85 an ounce was refused for high-quality gems, blue stones brought £45 an ounce, and second-grade stones realized 15 to 30s. an ounce.

Ceylon is changing its mining laws. The Revenue Office now determines gem-mining royalties, the land (both Crown land and that alienated by the Crown) to be exploited, and the location of the workings. Natives are to be trained, after the European method, to cut gems for beauty and not for weight. As Ceylon is a tourist center from which every globetrotter desires to bring a precious stone, prices are higher on the average than they are in Europe. A fine star ruby weighing 310 carats was found in Ceylon by Dr. D. P. E. de Silva late in 1941. Some 15 years ago one weighing 215 carats was found and sold for Rs. 85,000.

LESSER GEMS

Australia is the world's principal source of opals, and its output from 1936 to 1939 ranged in value from $40,000 to $75,000 a year. Since 1936 South Australia (1938, £4,750; 1939, £6,020) has been the principal producer, followed by New South Wales. Queensland's production is small (1938, £80; 1939, £50). In 1941 the fields were reported to be doing well and the diggers busy. The market for opals was said to be good.

The ancient turquoise mines of Madan are about 30 miles west of Nishapur, Iran (Bureau of Mines Mineral Trade Notes, January 20, 1942, pp. 26–28). The Iranian Government farms out the mines to operators for about $2,000 a year. When India, the principal market, is buying in quantity 150 men are employed; at present the demand is poor, and only 20 men are employed. As for most gem mines other than those producing diamonds, profits are small. Turquoise occurs as seams and nodules in brecciated trachyte porphyry. Mining consists of open pits, shafts, and tunnels. To minimize shattering, powder is used instead of dynamite. If the color of the gem does not change within 2 weeks of mining, it is likely to be relatively stable.

The stones are cut at Meshed, 75 miles from the mines. The Iranian market absorbs 10 percent of the product; of the remainder, the best goes to India, and the poorer qualities go to Mecca for the pilgrim

497779—43——98

trade. From June 21, 1936, to March 20, 1940, yearly exports have averaged about 822 kilos of cut and 825 kilos of uncut, worth, respectively, 884 rials and 19 rials per kilo (at 50 rials to the dollar, $17.68 and $0.38, respectively.)

Brazil produces a number of gem stones, notably aquamarine, pale emerald, tourmaline, amethyst, yellow and blue topaz, and citrine. The value of aquamarine exported is normally 10 times that of tourmaline. Exports are considerably larger than the declared value, recently estimated as $10,000. Minas Gerais is the principal producer. The war apparently reduced 1941 exports somewhat.

Chile exports considerable tonnages of green "onyx" to the United States through the port of Antofagasta.

Despite Government restrictions, zircon continued for a time to pass the Indochinese border into Thailand for cutting at Bangkok. As already stated, upon the outbreak of the war in the Pacific, Thailand ceased to be a source of zircon for the United States.

South-West Africa, normally a large producer of aquamarine, tourmaline, and other lesser gems, produced 4,075.031 kilos of gems in 1939. As Germany had been the chief buyer, trade languished after the war started.

MINOR NONMETALS

By Paul M. Tyler and Charles L. Harness [1]

SUMMARY OUTLINE

GRAPHITE

Demand for almost every quality of graphite rose sharply in 1941 in response to expanded industrial activity and soaring requirements of munitions industries. The increase in tonnage was greatest in respect to Mexican amorphous, but percentagewise the demand for crucible grades was greatest. Stocks of Madagascar flake graphite were only moderate at the beginning of the year, and procurement of additional supplies was complicated by the fact that the island was Vichy-controlled. Under British and American Government auspices, certain quantities of Madagascar flake graphite were loaded and shipped to the United States; but further increases in the demand for crucibles from shipyards and other establishments producing matériel threatened to force the crucible industry to substitute Ceylon plumbago, even though this would have involved going back to World War I practice and manufacturing crucibles that would last only about half as many heats as modern crucibles made with Madagascar flake. After Pearl Harbor, the Far Eastern situation worsened steadily, so that it seemed doubtful whether even Ceylon plumbago would be available in quantities adequate for British and American needs. On February 17, 1942, the War Production Board issued Order M-61 restricting the use of plus-35-mesh Madagascar flake graphite to the manufacture of crucibles for the war effort only and naming the Metals Reserve Co. as sole importer of graphite of this quality. The order permits use of fines in ladle stoppers.

Meanwhile domestic mining possibilities were actively investigated. The Southern Experiment Station of the Bureau of Mines, Tuscaloosa, Ala., obtained samples from abandoned mines in Alabama in cooperation with the State University. In tests of samples of the crude graphite by improved methods of beneficiation, the Bureau investigators found a wide variation in quality but succeeded in producing a medium-coarse flake product containing 85 percent or more carbon

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

with good recoveries. From a group of 22 samples, said to represent a fairly complete cross section of the district, an average yield of 33 pounds of coarse flake was obtained per ton of raw material. Samples from certain mines indicated a yield of about 30 pounds per ton of small-size flake, which would have industrial uses. Tests of these concentrates by crucible manufacturers indicated that Alabama graphite could be used, although it was not a wholly satisfactory substitute for Madagascar flake, owing to the absence of coarser screen sizes. The following comparison was given by Clemmer and associates:[2]

Screen analyses of Madagascar and Domestic No. 1 flake graphite

Mesh range	Weight, percent		
	Madagascar samples		Domestic sample
	A	B	
Plus-20	7.8	11.5	4.6
Minus-20, plus-35	65.7	59.4	17.9
Minus-35, plus-65	24.9	24.9	62.5
Minus-65	1.6	4.2	15.0
	100.0	100.0	100.0

Further experimentation subsequently was directed toward avoiding destruction of coarse flake in grinding, and preparations were made early in 1942 to foster new commercial production with the aid of Government financing. Geological investigations indicated the possibility of getting crucible-grade flake from Pennsylvania, and early in 1942 old mining areas in the Chester (Pa.) district were being prospected. Plans were also made to resume the production of small-flake graphite in Texas. During 1941, however, except for small shipments from the Ceylon Graphite Co. operations near Good Water, Coosa County, Ala., virtually all the domestic output of crystalline graphite was furnished by the St. Lawrence Graphite Co., which took over the properties of the Long Valley Ore Co. in St. Lawrence County, N. Y. Minor quantities were shipped from stock at Dillon, Mont.; Elberton and Royston, Ga.; and Omak, Wash.

As in former years, amorphous graphite for paint was mined by the Carson Black Lead Co. in Nevada, and artificial graphite was manufactured and sold by the Acheson Graphite Co. (30 East 42d Street, New York, N. Y.) at Niagara Falls and by the Exolon Co. at Blasdell, N. Y. Early in the summer of 1941 the low-grade anthracite-graphite deposits of the Graphite Mines Co. at Cranston (Providence), R. I., were being reopened after several years idleness. This material is used principally in foundry facings. In Canada the Black Donald Graphite Co., Calobogie, Renfrew County, Ont., continued to keep its mill running on material dumped during earlier operations. The mine seems to have been virtually worked out. Until recently much of this graphite, which is a very small flake, had been sold to American pencil-lead manufacturers; but in 1941 exports were prohibited, and the Canadian Government was investigating ways to revive graphite

[2] Clemmer, J. Bruce, Smith, R. W., Clemmons, B. H., and Stacy, R. H., Flotation of Weathered Alabama Graphitic Schist for Crucible Flake. Geol. Survey Alabama Bull. 49, 1941, 101 pp.

mining in the Dominion. Graphite claims at Sagalen Bay, Labrador, were said[3] to have commercial possibilities.

Notwithstanding the growing shortage of Madagascar and Ceylon graphite, prices were held down by suppliers. Typical quotations for carload shipments ex-dock, New York City, duty paid, in 1941 (1940 figures in parentheses) were as follows: Madagascar flake, 8 to 9½ cents per pound (6½ to 8 cents); Ceylon lump, 8 to 17 cents (7 to 15 cents); chip, 7 to 12 cents (5 to 10 cents); and dust, 3½ to 8 cents (3½ to 8 cents).

Ocean freight on Madagascar flake, which before the war was about $11 a ton, advanced in 1941 to as much as $40. The 1941 prices for Ceylon lump were only one-fourth to one-half what they were in the World War of 1914–18, when they ranged from 28 to 32 cents a pound.

During the first 9 months of 1941 imports of all grades of graphite totaled 20,051 short tons valued at $1,297,402. Figures for 1941 cannot be published by grade or by country of origin. Data for the entire year 1940 were: Flake, 6,551 tons valued at $340,396; lump, chip, and dust, 752 tons, $54,027; natural amorphous, 23,766 tons, $487,675; and total, 31,069 tons, $882,098.

Information on world production of graphite has been meager since 1938, when the output was over 140,000 metric tons. The following production data are for 1940: Madagascar, 15,311 metric tons; Ceylon, 24,414 tons; and Mexico, 12,327 tons. Mexican production in 1941 was 16,928 tons. A table covering the period 1915–39 appeared in Minerals Yearbook, Review of 1940, p. 1414.

GREENSAND

Shipments of greensand by four companies in New Jersey reached 11,120 short tons valued at $619,664 in 1941, compared with 6,697 tons, $389,888 (revised figure), in 1940 and 6,466 tons, $318,550 (revised figure), in 1939. In earlier years, the value recorded for greensand by the Bureau of Mines was that of the refined greensand produced. For 1941, the value is that of the product as sold—refined or processed further—and the values for 1940 and 1939 have been revised to this basis. Whereas refined greensand is available at $16 to $25 a short ton f. o. b. works, a large part of the output is processed further by the same companies that mine the raw sand and is sold as a water softener at prices up to $115 a ton. Although New Jersey greensands contain a small quantity of potash and phosphorus, very little is used as a fertilizer, the output being consumed almost entirely in water-softening compounds.

KYANITE, ANDALUSITE, AND DUMORTIERITE

Consumption of the sillimanite-group minerals increased sharply in 1941. Shipments of domestic kyanite by five firms rose to 8,335 short tons valued at $175,581, topping the previous all-time record (4,241 tons valued at $93,716) made in 1940. Notwithstanding the shortage of shipping space, imports of British Indian kyanite also increased in 1941; receipts during the first 9 months (the period for which figures can be published) amounted to 6,211 short tons having a foreign market value of $81,356, compared with the previous record of 7,658 tons valued at $92,159 in the full year 1940.

[3] Bureau of Foreign and Domestic Commerce, Foreign Commerce Weekly: Vol 5, No. 1, October 11, 1941, p. 31.

Andalusite is mined on White Mountain, Mono County, Calif., by Champion Sillimanite, Inc., Merced. The same firm—only domestic producer of either mineral in 1941—also ships dumortierite from its mine at Oreana, Pershing County, Nev., to the parent firm—Champion Spark Plug Co., Detroit, Mich.—which uses both materials in spark-plug cores and other electrical porcelains.

Celo Mines, pioneer producer of kyanite at Burnsville, N. C., suspended operations temporarily in 1941 but reopened later in the year as Mas-Celo Mines, Inc., subsidiary of Munn & Steel, Inc., 130 Lister Avenue, Newark, N. J.

One of the largest kyanite deposits in the United States is on Baker Mountain in Prince Edward County, Va., near Pamplin and about 20 miles from Farmville. As stated in several recent publica-

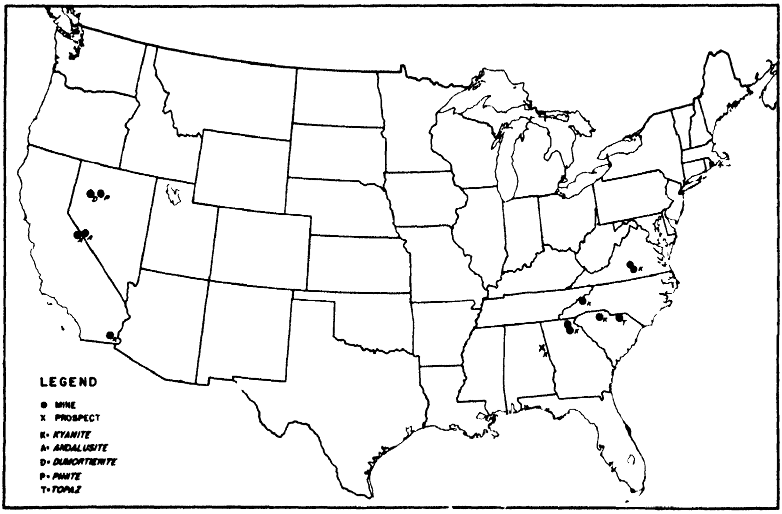

FIGURE 1.—Occurrence of minerals of the sillimanite group in the United States.

tions,[4] the kyanite occurs there in a quartzite schist as abundant massive kyanite-quartzite bodies with impurities such as rutile, hematite, pyrite, and quartz. To remove the impurities the quarried product is ground to at least 35-mesh and processed by flotation and magnetic separation, yielding a 93-percent kyanite concentrate which may be washed in acid to give an even purer product (0.32 percent Fe_2O_3).

A digest follows of a report by R. B. Heuer, chairman of the Nonmetals Group of the National Academy of Sciences Advisory Committee on Metals and Minerals, to the Office of Production Management in late 1941:

> The metallurgical industries account for about 50 percent of the total kyanite refractories used in the United States. Kyanite or other superrefractories (alumina, spinel, fused aluminosilicate, chrome, etc.) are not really needed in brass melting except for high-melting alloys, less than 25 percent of the total

[4] Hubbell, A. H., Preparing Baker Mountain Kyanite for Market: Eng. and Min. Jour., vol. 142, No. 10, October 1941, pp. 53-55.
Sawyer, J. P., and Whittemore, J. W., The Development of a Refractory Aggregate from Virginia Kyanite: Bull. Virginia Polytech. Inst., Eng. Exp. Sta. Ser. 49, November 1941, pp. 5-36.
Anderson, C. E., Electricity Furnishes Power for Kyanite Production in Virginia: Southern Power and Industry, vol. 58, No. 10, 1940, pp. 76-79; Ceram. Abs., vol. 20, No. 6, June 1941, p. 145.

tonnage. In ferrous melting, high-alumina refractories, which cost only one-fifth as much as kyanite products, are equally serviceable when temperatures are not too high, but above 3,000° F. the latter have twice the life. In smaller furnaces, fused alumina and magnesia linings have life equal to kyanite. Kyanite roofs in small, direct-arc, electric furnaces (1,000 pounds or less) will last longer than silica, even under continuous operation, and afford at least five times the life in intermittent operation. In the glass industry kyanite, due to its refractoriness, high density, resistance to corrosion, and low spalling, is in a class by itself in respect to feeders, plungers, and intricate shapes and is economical to use in the superstructure or bottom at various critical points. The chief ceramic use is in high-temperature kiln furniture for open-type firing in tunnel kilns. For laboratory test kilns for intermittent, extremely high temperature service, especially under load, kyanite has no general substitute, although fused cast products of mullite or high alumina have been used successfully on a limited scale. There are many miscellaneous minor refractory uses for kyanite which in the aggregate account for only 5 percent of the consumption. Many of these are intricate shapes that can be made from kyanite because the volume change in burning is negligible. Fire-clay products shrink on firing, and volume-stable products made from alumina or fused magnesia spall too much.

Shipping rates on kyanite from Calcutta increased from $11.20 to $16.80 a short ton during 1941, and the cost of Indian kyanite delivered at Atlantic seaports rose from about $25 to over $30 a short ton. Prices for domestic kyanite in 1941 ranged from $3 a short ton, works, for crudes to around $78 a ton f. o. b. plant for high-grade, low-iron domestic material ground to 325-mesh. Andalusite and dumortierite, virtually unknown on the open market, were arbitrarily valued at $10 to $15 a ton at the mine.

LITHIUM MINERALS

Shipments of lithium minerals and compounds reached 3,832 short tons valued at $115,718, a record for recent years, compared with 2,011 tons and $80,679 in 1940 (revised figures). Shortly before the World War of 1914–18, output was about 500 tons annually, with an average value of $20 a short ton at works. The largest production ever recorded was in 1920, when the total jumped to 11,696 tons valued at $173,002 owing to a sudden demand for lepidolite from California and New Mexico mines, but immediately thereafter production declined sharply and subsequently averaged less than 2,000 tons annually.

The quantity of lithium compounds required for the war program was not large in 1941 but may increase greatly. Hitherto the principal uses of the ores and salts have been in ceramics, glassware, air conditioning, and pharmaceuticals. Lithia is a powerful flux, particularly when used with feldspar, and is usually added to ceramic batches in the form of lithium carbonate, less often as ground spodumene or lepidolite. It improves the gloss, strength, and weathering-resistance of glazes. Relatively small quantities of lithia in glass insure working fluidity without sacrificing desirable physical and chemical properties. As ceramic bodies containing spodumene generally expand on firing, this property can be used to neutralize shrinkage exactly, and porosity can be reduced by a sintering operation in processing the raw material. A spodumene feldspar mixture that fuses at 6 or 7 pyrometric cone equivalents below the fusion temperature of pure feldspar has been placed on the market by the United Feldspar & Minerals Corporation, Spruce Pine, N. C., under the trade name Lithospar; the material is derived from pegmatites at Kings Mountain, N. C. A similar product is available from Tinton, in the Black

Hills of South Dakota. Additions of lepidolite mica afford a convenient source of alumina for opal or flint glass and increase the index of refraction and the toughness of the product. Amblygonite is rarely used directly in glassware or ceramics. Owing to its relatively high lithia content, this mineral is a preferred material for making lithium salts. A small amount of mixed lithium chloride and fluoride is used in welding-rod coatings.

The three principal shippers of lithium minerals and salts in 1941 were the American Potash & Chemical Co., producers of lithium-sodium phosphate from brines at Trona, Calif.; the Black Hills Keystone Corporation, whose output is largely lepidolite from the Black Hills of South Dakota; and the Maywood Chemical Works of Maywood, N. J., also working Black Hills pegmatites but recovering spodumene. The high price of lithium-sodium phosphate raises considerably the average price per ton of total lithium products shipped in the United States.

Use of lithium for high-conductivity copper castings more than doubled in 1941 compared with 1940, and its use in special bronzes is

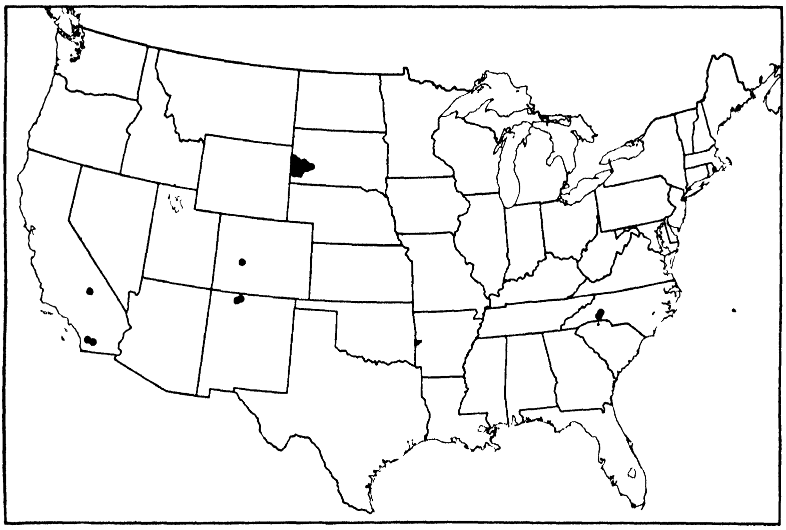

FIGURE 2.—Occurrence of lithium minerals in the United States.

now on a commercial scale. The element is added either in the form of a 50-50 lithium-calcium alloy or as an alloy of 98 percent copper and 2 percent lithium.[5]

Only small quantities of lithium minerals enter the open market. Nominal prices quoted by Engineering and Mining Journal Metal and Mineral Markets were unaltered during 1941 and for spodumene were \$5 per 20 pounds of contained lithia (Li_2O), 6 percent minimum, relatively iron-, quartz-, and tourmaline-free. Lepidolite, ordinary grade, lump, was quoted at \$24 to \$25 a short ton f. o. b. mine. Amblygonite, 8 to 9 percent Li_2O, was priced at \$40 a ton f. o. b. mine.

[5] Jeffries, Zay, Rare and Precious Metals Min. and Met., vol 23, No. 422, February 1942, p. 69.

MINERAL WOOL

Notwithstanding an estimated increase of 40 percent in dollar sales in 1941 over 1940, existing mineral-wool plants were able to handle the business. No new plants were completed during the year, although one was reported to be under construction in Missouri and another to be contemplated in Georgia. Unit prices of products were unchanged. The year-end forecast was for continued expansion, especially in pneumatic treatment of homes already built, due to fears of fuel shortage as well as to growing recognition of the true economy of insulation. Air-raid preparations also emphasized the fire-retarding properties of mineral wool. War Production Board orders to conserve metal for heating plants virtually required insulation of all new homes, heat losses being limited to 66 B. t. u. per square foot of floor area per hour per degree difference between inside and outside temperature.

MONAZITE

Formerly the only commercial constituent of monazite was thoria, which was used in gas mantles, and monazite is still marketed upon the basis of its thoria content, although commercial interest now centers on its content of ceria and other rare earth oxides. Probably 50 percent[6] of monazite derivatives are consumed (chiefly as fluorides) in the cores of arc carbons to increase lighting intensity in motion picture projectors, therapeutic lamps, and searchlights—in about that order. Pyrophoric alloys for use in sparking flints for cigar lighters take about 25 percent of the monazite consumed, and the remainder is distributed among a large variety of specialty uses, principally optical glassware. A summary of uses has been published elsewhere.[7]

The Consolidated Operations Corporation (reorganized in 1941 as Riz Mineral Co., 505 Park Street, West Palm Beach, Fla.) produced a small quantity of byproduct monazite in 1941 from rutile-ilmenite-zircon operations near Melbourne, Fla.

Nominal prices quoted by Engineering and Mining Journal Metal and Mineral Markets remained throughout 1941 at $60 a short ton ex-dock, 8 percent minimum thoria.

Beach deposits of black sands in Travancore in British India, along the coasts of Espirito Santo, Rio de Janeiro, and Bahia in Brazil, and in Netherlands Indies have supplied the bulk of United States monazite requirements in the past, as a byproduct in the recovery of ilmenite, rutile, and zircon sands. World production has been approximately 4,000 to 5,000 tons annually in recent years, British India furnishing over 80 percent and the remainder divided about equally between Brazil and Netherlands Indies. However, monazite has been produced from stream sands in the Piedmont region of the Carolinas, in Florida, and in Idaho. The domestic sands are lean and normally cannot compete with the Indian concentrates (8.8 to 10.1 percent thoria—ThO_2) or with Brazilian monazite (6 percent thoria). As mixed sands are imported under the same classification as high-purity monazite, the import statistics for different years are not always comparable.

[1] Quantities are gross weight; monazite content not reported.

OLIVINE

Shipments of olivine in 1941 rose to 4,828 short tons valued at $24,401, the highest tonnage since 1936. With the exception of a small quantity used in the production of Epsom salt, the entire output was consumed in refractories.

A review of olivine deposits of North Carolina and Georgia [8] estimates reserves of 230,000,000 short tons of high-grade forsterite olivine in the area, averaging 48 percent MgO. Domestic developments during 1941 have been reported elsewhere.[9]

Engineering and Mining Journal Metal and Mineral Markets in 1941 quoted crude North Carolina olivine at $5 to $7 a short ton at works; ground 200-mesh, $17 a ton; and 20-mesh to dust, $12 a ton.

QUARTZ CRYSTAL

Modern mechanized warfare depends upon instantaneous two-way radio communication, which to be effective must rely upon accurately ground wafers of crystal, two in each circuit; dozens are needed for a single tank or airplane. Brazil remains the only known commercial source of quartz suitable for radio-frequency control, and radio quartz crystal has been classified as a strategic mineral by the Army and Navy Munitions Board.

Quartz crystals of commercial size, found near Hot Springs, Ark., almost without exception show twinning, and crystal plates made from them do not have piezoelectric properties unless the twinned portion is cut away—a costly process. Cracks and inclusions of other minerals and of air render most domestic crystals and fragments subject to rejection, even before examination for piezoelectric properties.

In Brazil, the annual production of quartz crystal jumped to over 1,000 short tons in 1940 from about 250 tons in 1937. One-fourth of the output is consumed as piezoelectric (radio) quartz, and the remainder is used as optical, instrument, or fusing quartz. Before 1941 Japan's purchases were the backbone of the Brazilian crystal industry. The United States had comparatively small peacetime requirements and bought only high-grade material.

In 1941 the Governments of the United States and Great Britain agreed to buy all stocks of Brazilian quartz crystals remaining after

their nationals had made purchases for private industry. The Brazilian Department of Mineral Production, Ministry of Agriculture, introduced export control through licenses and levied a 10-percent tax based upon export prices. Exports may clear only through the ports of Rio de Janeiro and Salvador.

A schedule of prices for the various grades of crystal as of April 1941 has been reported.[10] For example, "A" (piezoelectric) grade crystals weighing 1.5 to 2.0 kilograms with growth faces were quoted at 250,000 milreis a kilogram (about $6, United States currency, a pound). Owing to tremendous increases in demand and slight revision in specifications for oscillator plates, many of the manufacturers began to use smaller crystals down to 200 grams each. Prices of larger crystals advanced as much as threefold during the year, but even at the peak these represented only a minor factor in the cost of the final product.

STRONTIUM MINERALS

Wartime requirements of strontium salts for tracer bullets and signal flares, superimposed upon increased civilian requirements for railway fusees and for superpurification of caustic soda for rayon manufacture, created a market in 1941 for celestite producers on the West coast, where the mines had been virtually idle since 1918. The total shipments of strontium minerals in 1941 amounted to 4,724 short tons valued at $69,054 compared with less than half that quantity in 1940. In peacetime, virtually all the strontium ore consumed in the United States has been British celestite, owing to its greater purity and the cheaper freight rates for ocean than for rail transport. Import data for the first 9 months of 1941 indicate increased receipts of celestite from England and substantial quantities from Mexico—a new source—the total imports in that period being 3,172 short tons valued at $49,367 compared with the 12-month receipts in 1940 of 2,751 tons valued at only $28,686.

The outstanding producer of strontium minerals sold for chemical purposes was the Pan Chemical Co., 205 First National Bank Building, Pomona, Calif., which worked an open-pit deposit near Westmoreland, Imperial County, Calif. Crude ground celestite for use in drilling-mud admixes was produced by three Texas firms in 1941: The Bennett-Clark Co., Inc., Nacogdoches (deposit at Sweetwater, Nolan County); the Milwhite Co., Inc., of Houston (deposit at Blanket, Brown County); and Mudrite Chemicals, Inc. (deposit at Blanket). Strontianite was produced by the Manufacturers Mineral Co., Seattle, Wash. (mine at La Conner, Wash.), and by C. Solomon of San Francisco, Calif. (mine at Barstow, Calif.).

A general review of the strontium-minerals industry was published by the Bureau of Mines in February 1942.[11]

TOPAZ

Promising results are being obtained in substituting properly calcined topaz for kyanite in refractories. The massive deposit in Chesterfield County, S. C., is now estimated to contain at least 60,000 tons of commercial topaz.

VERMICULITE

Vermiculite was shipped by six operators in 1941, and sales of crude and refined material totaled 23,438 short tons valued at $125,444 at works, compared with 22,299 tons valued at $137,698 in 1940 (revised figures). The Universal Zonolite Insulation Co. (2601 West 107th Street, Chicago, Ill.), operating properties at Libby, Mont., remains the predominant producer and processor, with 47 plants, although smaller producers have developed local markets.

Standard uses for expanded (heat-treated) vermiculite are as house fill; in insulating, acoustical, and lightweight plasters; in cements; and in coatings. When ground it may be used in aluminum and bronze powder paints as an extender or replacement, and this outlet may be developed further in view of metal shortages.

North Carolina reserves of commercial-grade vermiculite have been estimated [12] at 250,000 to 500,000 tons. Recent tests by the University of North Carolina laboratories indicate that local vermiculites are equivalent to and interchangeable with the western product. Houses using precast North Carolina vermiculite wall panels and vermiculite concrete flooring were erected in 1941. In St. Louis, Mo., poured slabs of vermiculite concrete were used successfully in the roof of a large, new, small-arms factory; 180 carloads of vermiculite were used on this job alone. In North Carolina, vermiculite fines have been used ni the inner soles of shoes.

Little or no run-of-mine vermiculite enters the domestic market. Virtually all is screened and cleaned at the mine, and some is exfoliated by the producer or may be sold to a processor for heat treatment. Screened vermiculite from Montana and Wyoming operations was sold to processors at $5 to $10 a short ton f. o. b. mine. Screened North Carolina vermiculite was sold at $10 to $15 a short ton f. o. b. mine. Western exfoliated material was quoted at $40 to $55 a short ton and North Carolina at $35 to $45 f. o. b. works.

PART IV. MINE SAFETY

EMPLOYMENT AND ACCIDENTS IN THE MINERAL INDUSTRIES

By W. W. ADAMS

SUMMARY OUTLINE

INTRODUCTION

Employment in nearly all branches of the mineral industry of the United States made gains during 1941, according to information sent by operating companies to the Bureau of Mines. Although reports received thus far do not cover all active operations, they reveal that of the 22 groups of mineral industries for which separate figures have been compiled 17 groups employed more men and 20 worked a larger aggregate number of man-hours than in 1940; these 22 classes are listed in an accompanying table. As far as can be judged from information now available, the only groups that experienced a reduction in total employee-hours worked during 1941 were gold placer mines and marble quarries, both of which apparently suffered a loss in number of employees and in man-hours worked.

The increase in number of employees and in total man-hours of work performed during the year were natural results of war demands for mineral products.

With larger volume and accelerated tempo of work came a larger number of injuries from accidents to employees. Fortunately, the number of fatal accidents decreased; the number of nonfatal lost-time injuries was larger than in 1940. The gain in man-hours worked, however, prevented a large rise in the accident-frequency rate (number of accidents per million man-hours of work) which was only slightly higher in 1941 than in 1940. The rate for fatal accidents was reduced, so the slight increase in total accident frequency was solely in the rate for nonfatal injuries.

A review of employment and accidents in the mineral industries of the United States for the 11 years 1931-41 shows that the number of employees reached a maximum in 1937. The maximum volume of

employment, as measured by man-hours of work performed, however, was attained in 1941, according to estimates based upon the latest available information; this achievement may doubtless be attributed to work required to supply domestic and foreign demands that can only be met, directly or indirectly, by greater production of minerals in the world's largest mineral-producing nation.

Number of men employed in the mineral industries of the United States, 1939–41

	1939	1940	1941 [1]
Coal mines:

[1] Subject to revision.

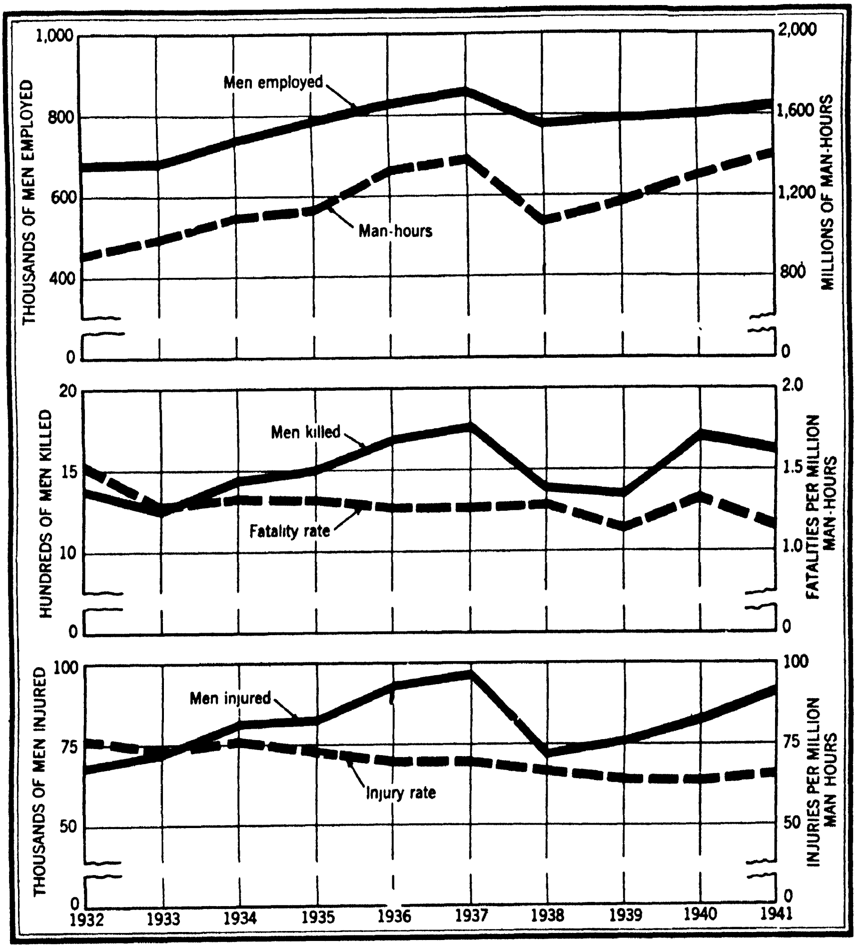

FIGURE 1.—Trend of employment and fatal and nonfatal accidents in the mineral industries of the United States, 1932–41.

EMPLOYMENT AND ACCIDENTS

BITUMINOUS-COAL MINES

Employment.—About 666,000,000 man-hours of work were required to furnish the United States with approximately 504,577,000 short tons of bituminous coal in 1941. This work was done by a labor force estimated at 448,000 men. The mines were in operation for about 213 days per man. Seven hours was the standard daily work shift. These estimated figures indicate an increase of about 43,000,000 tons in production, of about 7,000 employees, and of the work year by an average of 12 days per man.

Accidents.—Although fatal accidents (now estimated at 1,064) were less numerous during 1941 than in 1940, the estimated number of nonfatal injuries to employees rose from nearly 44,000 to more than 47,000; and the larger number of nonfatal accidents caused a small increase in the rate per million man-hours of exposure, as the tentative rate was 71 in 1941 compared with 70 in 1940. The year 1941 was marked by 2 more major disasters in the mines than in the preceding year—8 compared with 6 in 1940; however, 73 men were killed by major disasters in 1941 compared with 276 in 1940.

The eight major disasters during 1941 were not confined to any particular State; two occurred in Illinois, two in Alabama, and one each in West Virginia, Kentucky, Pennsylvania, and Indiana. All the major disasters were explosions except the one in Illinois, which was due to explosives.

Even though 1941 had two more major disasters than 1940, the over-all fatality rate from all causes was only 1.60 per million man-hours of exposure, indicating a much better record in this respect than in 1940, when the rate was 1.92.

More than half of the total number of workers at all classes of mines and quarries are employed in bituminous-coal mines. Four-fifths of all fatal accidents and three-fourths of all nonfatal accidents in the mineral industries also occur at bituminous mines. Special importance therefore attaches to the accident record of the industry that has such a determining influence on the over-all accident costs incident to the production and development of the mineral resources of the United States.

Yearly records of fatal accidents at bituminous-coal mines are available for all States, covering all years beginning with 1910, and for the principal coal-producing States back to 1906. Similar records on nonfatal accidents are available only since 1931. These records show that the chief cause of both fatal and nonfatal accidents is falls of roof and coal. The actual number of deaths and injuries from this hazard has been greatly reduced, but the accident rates per million man-hours do not show an equal decline because the number of employees and man-hours has also been reduced. The reduction in employment without an equal loss in production of coal has been made possible by the rapid mechanization of many operations that formerly were carried on by hand or with hand-operated tools, such as drills, picks, and shovels. Productivity per man-hour worked has therefore increased, and the coal industry has been able to supply the fuel needs of the country with fewer men exposed to the accident hazards of mining. Simultaneously, accident-prevention programs of mining companies have been effective in reducing the number of accidents;

but the reduction in accidents has resulted in only a slight downward trend in accident rates per million man-hours of exposure over a period of years. An important factor inherent in any Nation-wide effort to reduce the per-million-man-hour accident rate from falls of roof and coal is the difficulty attending the safety training of around 300,000 men in the mines, the employees at the "working face," who, more than other classes of underground employees, are exposed to the falls-of-roof hazard.

Haulage accidents rank next to falls of roof among the occupational hazards to which coal miners are exposed. The long-time trend of accident rates for accidents of this class is upward. Contributing causes are probably the lengthening of haulageways following the extension of mined-out areas underground and the use of larger cars and their more rapid movement because of increasing productivity per man-hour of labor incident to the replacement of hand methods by machine methods of work; thus production is being accelerated without a corresponding increase in the intensity and scope of accident-prevention methods and installation of safety appliances. The vital part of haulage operations in the production of coal and the upward trend in accidents that involve haulage equipment suggest the importance of special study by mining companies and others of means whereby haulage accidents to the mine workers may be reduced.

Fortunately, gas and dust explosions that occurred so often and on so large a scale in earlier years have been greatly reduced in frequency and severity, both absolutely and in relation to the number of man-hours of exposure to risk. Even in recent years, such explosions have occurred all too frequently, but the progress made by the coal industry in preventing loss of life from this class of accidents will become apparent to anyone who examines the record of the coal-mining industry.

Accidents directly chargeable to explosives have likewise been greatly reduced, both absolutely and relatively. Much of this improvement may be credited to the adoption of "permissible" explosives by mines that formerly used more dangerous types of explosives, usually black blasting powder.

Electricity, although not the chief mining hazard because relatively few accidents result from its use compared with those from haulage and from falls of roof, is nevertheless among the risks to which coal miners are exposed because of its major role as a source of power for operating mining machines and mine haulage motors. The fatality rate from electricity, though not as high as those for roof falls and haulage, is higher than it was when electric current was used less extensively in mining. The increasing application of electric power in coal mines demands special study by safety engineers.

ANTHRACITE MINES

Employment.—This group includes all mines in the eastern part of Pennsylvania that produce coal generally known as "hard coal" or "anthracite." Output from legitimate mines, as distinguished from so-called "bootleg" operations, amounted to about 54,000,000 short tons in 1941 and required the work of approximately 88,900 men for 130.1 million man-hours. According to tentative figures now available, the number of employees was slightly less than in 1940 but

the total man-hours worked was greater. The average employee worked about 18 workdays more than in 1940.

Accidents.—Accidents to men working in and about the mines and breakers caused 194 fatalities and 16,828 nonfatal lost-time injuries. Final reports for 1941 probably will show a fatality rate of about 1.49 and a nonfatal-injury rate of about 129 per million man-hours worked. The combined accident frequency rate is slightly less favorable than that of 1940. No major disaster occurred in 1941; in fact, no major disaster has occurred in an anthracite mine since June 2, 1938, when 10 men were killed in an explosion in a mine in Luzerne County.

IRON-ORE MINES

Employment.—The demand for iron to meet the needs of American industry in the general war program of the United States continued to move the trend of employment at iron-ore mines upward during 1941. Incomplete reports from operators indicate a 15-percent increase in man-hours worked. The gain in number of men employed was relatively small, as the estimated number of employees in 1941 was 23,800 compared with 23,250 in 1940. In 1941 the average employee worked 275 days and thus had 32 more days of employment than in 1940. Man-hours of labor in 1941 numbered about 52,000,000.

Accidents.—Available reports indicate that 45 men were killed by accidents at iron-ore mines during 1941; 35 men were killed during 1940. Reports for 1941 also indicated that 1,158 employees received nonfatal injuries that caused them to lose time from their work. The accident-frequency rate rose from 19.63 in 1940 to 23.08 (tentative) in 1941. These figures include a fatality rate of 0.77 in 1940 and 0.86 in 1941. Among the major metal-mining industries in the country, iron-ore mines consistently report the lowest accident-frequency rate. The preponderance of open-cut mines in Minnesota is partly responsible for this favorable record, although the unflagging prosecution of safety programs by the operating companies is doubtless the most potent factor.

COPPER MINES

Employment.—Reports for copper mines in 1941 showed continued gains in number of employees and man-hours worked. Approximately 21,500 men were engaged in mining copper ore, and they labored approximately 55,000,000 man-hours during the year. These figures relate to mines whose chief product was copper; they do not cover mines whose ores, though containing some copper, were valuable chiefly because of their content of some other metal. Judging from reports now available, the workyear 1941 averaged 319 days per man, an increase of 7 days for the average worker. The total man-hours worked in the industry as a whole represent a 13-percent gain over 1940.

Accidents.—The increased employment in 1941 brought in its train a larger number of accidents to employees. The fatality rate, as at present estimated, was 1.11 compared with 0.99 in 1940; the tentative rate for nonfatal injuries was 53.14 compared with 52.91. Sixty-one of the accidents in 1941 resulted fatally; an estimated 2,920 were nonfatal lost-time injuries.

LEAD AND ZINC MINES (MISSISSIPPI VALLEY STATES)

Employment.—This group comprises all lead- and zinc-producing mines in the Mississippi Valley States, chiefly Oklahoma, Missouri, and Kansas; it also includes mines in Illinois and Kentucky that produce fluorspar. Fluorspar mines in these two States are included for two reasons: First, it is desirable to maintain unbroken a statistical series in the Bureau of Mines accident records that extends back to 1911. Second, natural conditions regarding safety are similar in the two classes of mines in the States named. Therefore, by combining the two classes of mines, the number of operating companies becomes large enough to permit separate figures to be published for Illinois and Kentucky. With this explanation, it may be stated that mines in the Mississippi Valley States employed about 7,900 men in 1941, an increase over the 7,644 men employed in 1940. Man-hours of employment rose from 13.7 million in 1940 to 16.4 million in 1941, or more than 19 percent. The average employee had a longer workyear than in 1940.

Accidents.—From reports now available, the accident-frequency rate for 1941 appears to have been 52.08 per million man-hours, which compares favorably with the rate of 56.92 for 1940. The rate for 1941 is based upon an estimate of 855 injuries, including 19 fatalities.

GOLD AND SILVER MINES (LODE AND PLACER)

Employment.—This group includes not only mines that were operated chiefly for the gold or silver contained in their ores but also lead and zinc mines outside the Mississippi Valley States and mines that produced some copper but whose ores were valuable chiefly because they contained metal other than copper. Placer mines as well as lode mines are included in the group.

The group as a whole employed about 55,400 men in 1941 compared with 54,829 in 1940. Man-hours of employment increased from 94.1 to 95.4 million. The fact that the group did not show a loss in employment probably can be attributed to the inclusion of mines whose ores contained some copper, zinc, or lead.

Accidents.—Tentative figures now available reveal that the accident-frequency rate for this group of mines was 102.55 per million man-hours, which compares unfavorably with the rate of 97.43 for 1940. Accidents during 1941 caused injuries estimated at 9,784, including 103 fatalities

MISCELLANEOUS METAL MINES

Employment.—This group includes all mines that produce metallic ores exclusive of gold, silver, copper, lead, zinc, and iron; these mines yield such strategic minerals as tungsten, mercury, manganese, bauxite, and molybdenum, as well as various other metals. Tentative figures now available suggest that war production was an influencing factor in raising the employment figures in 1941 to approximately 5,400 men, or more than 5 percent above the 5,119 men employed in 1940. The man-hours of employment rose from 10,000,000 to nearly 12,000,000, or more than 19 percent.

Accidents.—The safety record for mines in the "Miscellaneous metal-mines" group was less favorable in 1941 than in 1940. The accident frequency rate per million man-hours of employment rose to approximately 74.32 from 68.87 in 1940, including a fatality rate of 0.80 in 1940 and an estimated fatality rate of 1.25 in 1941.

NONMETALLIC-MINERAL MINES

Employment.—This group comprises mines that yield any kind of nonmetallic mineral except coal, stone, sand, gravel, and clay. It therefore includes mines that produce phosphate rock, rock salt, sulfur, gypsum, feldspar, barite, and many other minerals. Employment in 1941 was 10,600 men, an 8-percent increase over the 9,780 men employed in 1940; whereas the man-hours of employment in 1941 totaled 22,000,000 compared with 19,000,000 in 1940, an increase of approximately 17 percent.

Accidents.—Tentative figures to date reveal that the accident-frequency rate for 1941 was 48.64 per million man-hours worked; this compares unfavorably with the rate of 44.24 for 1940.

CEMENT MILLS AND QUARRIES

Employment.—Increased employment was reported in the cement industry in 1941; approximately 28,600 men were employed, or 7 percent more than in 1940. The men worked an estimated 63,000,000 man-hours, an increase of 15 percent. The men averaged 305 days of employment during the year and thereby gained 27 days per man over the average work period in 1940.

Accidents.—The rise in employment at cement plants in 1941 was accompanied by an increase in the total number of accidents to employees; 14 men were killed, and about 692 were injured. These accidents resulted in a fatality rate of 0.22 per million man-hours of employment, a decrease from the previous year's rate of 0.27. The nonfatal-injury rate was 10.90 per million man-hours compared with 9.44 in 1940.

MARBLE QUARRIES

Employment.—Employment at marble quarries and related operations continued the downward trend in employment that began in 1940. An estimated 2,500 men were employed, or more than 700 men less than the total of 3,240 in 1940. Man-hours of employment amounted to approximately 4.9 million, a decrease of 19 percent from 1940.

Accidents.—Preliminary figures indicate that no fatalities occurred in the marble industry during 1941. Although the number of accidents probably will show little change from 1940, the accident-frequency rate per million man-hours of employment will show a decided increase because of the large drop in man-hours worked The rate for 1941 is estimated at 49.70 compared with 40.82 for 1940.

SLATE QUARRIES

Employment.—Although the number of men employed in the slate industry decreased in 1941, according to preliminary figures, the number of man-hours of employment increased, indicating a longer workyear per man. It is estimated that 2,700 men worked 5.4 million

man-hours and that the average employee had 19 more workdays during 1941 than during 1940.

Accidents.—One man was killed and 330 were injured in 1941 in the course of their employment. The fatality rate for 1941 was 0.19 and the nonfatal-injury rate 61.46, corresponding rates for 1940 being 0.20 and 70.83, respectively.

TRAPROCK QUARRIES

Employment.—The traprock industry employed 2,700 men in 1941, according to preliminary reports to the Bureau of Mines. These men worked 4.9 million man-hours. The man-hours of employment represent a gain of about 15 percent over the 1940 total compared with a loss of nearly 9 percent in the number of employees.

Accidents.—Four men were killed in 1941. Approximately 334 men suffered nonfatal lost-time injuries from accidents during their employment. The fatality rate was 0.82 and the nonfatal-injury rate 68.08, compared with 0.70 and 62.94, respectively, in 1940.

GRANITE QUARRIES

Employment.—Employment at granite quarries rose in 1941 over 1940, according to preliminary figures; about 7,300 men were employed, an increase of approximately 2 percent. These men worked an average of 238 days each, or 15 more days per man per year than in 1940. The number of man-hours worked reached approximately 14,000,000, a gain of 14 percent.

Accidents.—Nine men were killed and 694 injured, resulting in a fatality rate of 0.64 per million man-hours of exposure and a nonfatal rate of 49.51. Although the fatality rate in 1941 was lower than the rate of 0.98 in 1940, the nonfatal-injury rate increased over the rate of 44.26 in 1940.

SANDSTONE QUARRIES

Employment.—The number of men employed at sandstone quarries and related plants increased in 1941, the tentative figure being 3,400 compared with 3,078 in 1940. Man-hours of work also made a substantial gain and totaled 6,000,000, a considerable advance (24 percent) over the 4.9 million hours worked in 1940. The average days of employment also increased, apparently about 26 days per man over the average of 199 workdays per man in 1940.

Accidents.—Accidents in sandstone quarries resulted in 2 deaths among the employees, giving a fatality rate of 0.31 per million man-hours of exposure to risk. It is estimated that 348 nonfatal injuries occurred among the employees. This estimate indicates an injury rate of 57.48 compared with 50.80 for 1940.

LIMESTONE QUARRIES

Employment.—The number of men employed in limestone quarries was 8 percent greater than in 1940, or an estimated total of 25,100 men; these figures do not include employment at limestone quarries at which the stone was used in manufacturing cement or lime. The man-hours of employment increased 20 percent, or in larger proportion than the men employed. A total of nearly 45,000,000 man-hours was worked during 1941 compared with 37,000,000 in 1940.

Accidents.—Accidents caused the death of 24 men and nonfatal lost-time injuries to approximately 2,436. The combined accident-frequency rate for 1941 was 55.01, and for 1940 it was 53.10.

LIMEKILNS AND QUARRIES

Employment.—Men employed, man-days, and man-hours at quarries producing limestone for the manufacture of lime increased in 1941, according to preliminary reports from operating companies to the Bureau of Mines. Approximately 11,100 men were employed for a total of more than 24,000,000 man-hours. The average number of days of work per man differed little in 1941 from 1940.

Accidents.—Accidents increased in greater proportion than employment, as revealed by an accident-frequency rate of 63.61 compared with 47.60 in 1940. The 1,565 accidents estimated for 1941 included 15 fatalities and 1,550 nonfatal injuries.

BYPRODUCT COKE OVENS

Employment.—Employment at byproduct coke ovens advanced in 1941. Complete reports indicate that 18,600 men were employed and that nearly 54,000,000 man-hours were worked compared with 17,469 men and about 50,000,000 man-hours in 1940. The number of men employed was 6 percent greater and the number of man-hours of employment 7 percent greater than in 1940.

Accidents.—Twelve men were killed and 435 men injured at byproduct coke ovens in 1941. The fatality rate was 0.22 and the nonfatal-injury rate 8.07 per million man-hours of employment compared with 0.30 and 7.94, respectively, in 1940.

BEEHIVE COKE OVENS

Employment.—The number of men employed at beehive coke ovens in 1941 rose 60 percent to a total of 4,000. These men performed 7,000,000 man-hours of work during the year, or more than twice the hours worked in 1940. The number of employees at beehive coke ovens reached a higher figure in 1941 than in any year since 1926, and the number of man-hours of employment was greater than in any year since 1927.

Accidents.—For the first time since 1937, fatalities occurred during operations at beehive coke ovens. Three men were killed in 1941, and these accidents resulted in a fatality rate of 0.43 per million man-hours of exposure. In all, 367 men suffered nonfatal lost-time injuries, resulting in a nonfatal-injury rate of 52.71, which compares unfavorably with the 1940 rate of 44.00 per million man-hours.

ORE-DRESSING PLANTS

Employment.—Ore-dressing and beneficiating plants or mills employed approximately 14,400 men in 1941 compared with 13,990 in 1940. The plants, considered as a group, were in operation 33,000,000 man-hours; this figure reveals a 7-percent gain over the record of nearly 31,000,000 man-hours worked in 1940.

Accidents.—Accidents to men employed at the mills occurred at the rate of 27.38 per million man-hours, a rate that compares favorably with 31.99 in 1940.

SMELTERS

Employment.—The smelting industry, as the term is here used, covers the smelting and refining of all metallic ores except iron ore. Employment and accident statistics covering iron-ore smelting and steel manufacturing are collected and compiled by the United States Department of Labor and hence are not included in Bureau of Mines figures. The smelting industry, as thus defined, employed approximately 21,300 men in 1941, an increase of nearly 6 percent over the 20,120 men employed in 1940. The man-hours of employment totaled 53.4 million in 1941 compared with 46.8 million in 1940, an advance of 14 percent.

Accidents.—Accidents to men employed at smelters in 1941 occurred at the rate of 24.77 per million man-hours worked. As the corresponding rate for 1940 was 19.71, it is apparent that the safety record of 1941 was unfavorable.

AUXILIARY WORKS AT ORE-DRESSING PLANTS AND SMELTERS

Employment.—Auxiliary works cover all operations at mills and smelters not directly connected with milling and smelting processes. About 16,500 men were employed in 1941, 10 percent more than the 14,958 employed in 1940. Man-hours worked increased to 40.5 million from 35.3 million in 1940, or 15 percent.

Accidents.—Tentative figures reveal an accident-frequency rate of 22.88 per million man-hours in 1941. The 1940 rate of 19.44 indicates a less-favorable safety record in 1941. Accidents during 1941 are estimated at 927, including 10 fatalities.

SUMMARY, 1932–41

While the Nation is at war, loss of manpower in industry means loss of time needed to produce essential war materials. Accidents disabling employees in the mining, quarrying, and related mineral industries referred to in this chapter not only cost the men who work in these industries suffering and loss of income but also hamper the Nation in its effort to obtain maximum production of war materials. During 1941, for example, temporary injuries alone caused an estimated loss of approximately 3.3 million man-days to the war-production program of the United States when our country was aiding nations that after December 7 became our Allies. Additional losses were caused by accidents resulting in the death of injured employees and by other accidents causing permanent, total, or partial disablement. They cannot be stated in terms of man-days except in the customary way of considering that an industrial accident that kills an employee thereby destroys 6,000 days life-expectancy of usefulness in industry, that a similar loss results from each case of permanent total disability, and that some part of 6,000 days of usefulness in industry is destroyed by each case of permanent partial disability, the exact amount depending on the severity of injury and the part of the body affected. Usual methods of considering deaths and permanent injuries suggest a loss of more than 12,500,000 man-days because of such accidents during 1941. Thus, all classes of accidents in the mineral industries during 1941 may be fairly considered to have destroyed nearly 16,000,000

man-days of labor that might have otherwise contributed to the production of mineral commodities during the present war and, later, during the years of peace.

In bituminous coal-mining alone, and considering temporary injuries only, the loss of about 1.7 million man-days from accidents during 1941 meant that nearly 9,000,000 more tons of coal could have been produced in that year.

Losses of manpower such as those described here challenge the ingenuity of mine managers and the cooperative spirit of mine employees. Such losses, greater or less, are but every-year experiences in the United States, a fact demanding investigation at least equal in continuity and intensity to that often applied to problems apparently more important commercially.

The marked success that attends the accident-prevention programs of many mining companies indicates what may be accomplished by other operators in the saving of life and limb and in promoting contentment among the large group of Americans who have chosen the production of minerals as their life work. Both humanitarian and monetary considerations suggest that maximum effort of employees, operators, and Government be devoted to attaining these great objectives.
